BRADFORD MEDICO-CHIRURGICAL SOCIETY.—At the ordinary monthly meeting of this society held on Jan. 8th, Dr. Samuel Johnston, President, in the chair, Dr. T. W. Hime introduced a discussion on Precautionary Measures for the Prevention of Tuberculosis. The importance of tuberculosis was insisted on because of its always being present, because of its great death-rate, and the number of persons it attacks, giving rise to prolonged illness and attacking adults. It has been estimated that one-seventh of the human race die from tuberculosis. In 1890 there were 68 000 deaths in England from tuberculosis, the mortality not being known owing to the actual number of cases being uncertain. That recovery from tuberculosis does take place is proved by the presence of cicatrices in the apices of lungs. The pathology of tuberculosis was briefly glanced at, its bacillary origin and its local origin being alluded to. The mortality from tuberculosis since 1854 has been steadily falling from 34 per 1000 to 24 per 1000 in 1890, although no special crusade has been directed against it beyond general sanitary improvements. In cases of phthisis the great danger arises from the expectoration becoming dry and being blown about as dust. To prevent this Dr. Hime advocated the use of portable spittoons. Handkerchiefs should be avoided, and if used should not be washed with other clothes. Public spittoons should be provided at railway stations and in concert-rooms. Cases of phthisis should not be treated in the wards of general hospitals; special hospitals for tuberculous cases should be provided. The public should be educated with regard to the importance of using spittoons, especially in schools, workshops, hotels, lodging houses, prisons, and barracks. Other measures which Dr. Hime recommended were the notification of cases of tuberculosis, the disinfection of infected houses, and the watering of streets before they were swept. In Belgium there was compulsory notification of tuberculosis in animals, and in Denmark £3000 a year were voted for carrying out experiments on animals affected with tuberculosis. In conclusion, Dr. Hime emphasised the fact that tuberculosis was not spread by vaccination. The paper was discussed by Drs. Johnston, Major, Goyder, Kerr, Mr. Horrocks, Drs. H. Bronner, Drury (Halifax), Bell, and T. C. Denby, and Dr. Hime replied.

LIVERPOOL MEDICAL INSTITUTION.—At the annual meeting of the institution held on Jan. 10th the following list of office-bearers, council, and pathological and microscopical committee was adopted; those marked (*) did not hold the same office last year. President: Chauncy Puzey, F.R.C.S. Vice-Presidents: C. G. Lee, M.R.C.S., J. W. Warburton, M.D., *W. Macfie Campbell, M.D., *G. G. Hamilton, F.R.C.S. Edin. Hon. Treasurer: A. Bernard, M.B. Hon. General Secretary: *R. S. Archer, M.D. Hon. Secretary to Ordinary Meetings: Charles H. Shears, M.R.C.S. Hon. Librarian: K. Grossmann, M.D. Council: T. R. Bradshaw, M.D., J. E. Gemmell, M.B., J. Middlemass Hunt, M.B., Rushton Parker, F.R.C.S., G. S. Stansfield, M.R.C.S., *H. G. Rawdon, F.R.C.S. Edin., *R. W. Murray, F.R.C.S., *W. T. Thomas, F.R.C.S., *A. H. Wilson, M.R.C.S., *Richard Williams, M.R.C.S., J.P., *R. J. Hamilton, M.R.C.S., and *F. C. Larkin, F.R.C.S. Auditors: *G. S. Stansfield, M.R.C.S., *William Crozier, M.R.C.P. Irel. Pathological and Microscopical Committee: J. H. Abram, M.D., F. H. Barendt, M.D., F.R.C.S., A. Barron, M.B., *Rubert Boyce, M.B., A. W. Campbell, M.D., T. B. Grimsdale, M.B., G. G. Hamilton, F.R.C.S. Ed., F. C. Larkin, F.R.C.S., J. R. Logan, M.B., R. W. Murray, F.R.C.S., Frank T. Paul, F.R.C.S., W. T. Thomas, F.R.C.S., and Joseph Wiglesworth, M.D.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Abeles, formerly a physician in Carlsbad and a writer on many chemical subjects of clinical interest, especially on the occurrence of sugar in the urine. He died in Vienna, where he was a recognised Lecturer in Internal Medicine.—Dr. Spitzer, who soon after graduating in Vienna was appointed Professor of Anatomy in Constantinople, where he had to organise the medical school, an undertaking which was fraught with numerous difficulties. He, however, succeeded in establishing the school and was appointed Director. He gained the confidence of the Sultan Abdul Medjid by curing him of a severe illness, and was appointed His Majesty's body physician. Of course, the Imperial favour brought with it a great deal of opposition and misrepresentation from his rivals, and he found matters becoming so unpleasant that he requested leave to retire from Constantinople, which he did in 1850. Some years later the Sultan appointed him Ottoman Agent in Naples, which post he held until His Majesty's death in 1861. Since that time he had occupied himself with literary and scientific work, living sometimes in Paris and sometimes in Vienna, where he died at the age of eighty-one.—Dr. Cuzzi, Professor of Clinical Midwifery in the University of Pavia.—Dr. E. Bailly, formerly *professeur agrégé* in the Paris faculty of medicine.—Dr. Sim, Professor of Medicine, Memphis Hospital College.—Dr. Otton Marsh-novich Dannenberg, the oldest surgeon in the Russian army. He was born in 1807, and took his diploma as Medical Practitioner at Dorpat in 1831.

MANCHESTER MEDICAL SOCIETY.—The annual meeting was held on the 9th inst. in the society's reading-room at Owens College, Dr. Dixon Mann, the retiring president, being in the chair. The officers for the ensuing year were appointed, and Mr. F. A. Southam was elected president. His name is well known in Manchester, for his father was for many years a distinguished surgeon to the Royal Infirmary, and the son worthily holds a similar appointment. The report stated that the society had completed its sixtieth year and was in a satisfactory condition. "The number of members had increased, the finances were sound, the library was richer in medical literature and more patronised, and increasing interest was taken in the meetings." There are now 280 members, as compared with 268 at the end of 1893. Some changes were made in the laws, which have undergone revision, the most important being the reduction of the annual subscription from two guineas to one guinea. This will be a popular change, and extend the benefits of the society to a larger medical circle. It may be that the competition of the youthful but very prosperous Clinical Society has been felt as a stimulus, but the fact remains that membership of the two societies will now cost two guineas instead of three, and many will be glad to join both. The library now contains 31,230 volumes, in addition to a large number of pamphlets. Facilities are granted for the use of books to the students of medicine, and last year the number of volumes issued to them was 5851. The ordinary members have also made increased use of the library during the past year.

LITERARY INTELLIGENCE.—We have received the first number of a new medical monthly magazine, entitled *Clinical Sketches Illustrative of Medicine and Surgery*. The contents, if not quite fulfilling the promise of the title, are of an interesting and varied kind, prominent among them being four papers on Diphtheria, comprising an account of its bacteriological diagnosis and directions for the use of antitoxin serum. Illustrations of a finished and pictorial character are a special feature. Among these we may mention two views of Sidmouth and a full-page reproduction of Harvey's portrait preserved in the Royal College of Physicians, London. The paper is edited by Mr. Noble Smith, F.R.C.S. Edin., who is to be congratulated on his opening number. The publishers are Smith, Elder, and Co., 15, Waterloo-place, W.

BOURNEMOUTH MEDICAL SOCIETY.—At a meeting of this society held on Dec. 21st, 1894, Mr. Parkinson, President, in the chair, a resolution was passed expressing regret at the death of Dr. Bisset Hawkins, one of the honorary members. Dr. Andrew and Mr. Hale were elected honorary members, and Dr. Ringer and Dr. Fosbery ordinary members. Dr. Muspratt showed a case of Peculiar Skin Affection. On the radial side of the second phalanx of the left forefinger was a raised ring about as large as a sixpence. The history was that it had begun as a slight wart and had extended at the periphery, while the natural skin became restored in the centre. The patient was a healthy girl aged about twenty. It was not tender, and there was nothing in her occupation to account for it. Mr. F. Fred. Gardner showed a case of Deformity of the Scapula. Mr. Bernard Scott showed a patient in whom he had removed the internal semilunar cartilage from the knee. Mr. Mahomed read notes of a post-mortem examination in a case of Acute Dilatation of the Stomach, with short notes of the history. The affection arose during convalescence from pleuro-pneumonia and was rapidly fatal; the patient was a man twenty years of age. Mr. Mahomed gave a *résumé* of the literature on the subject and argued that excessive secretion was a factor in the disease besides the loss of muscular power in the stomach walls. He found that in all the recorded cases the history showed the existence of some primary disease in the vagus tract. Mr. Kemble read notes of a case of Convulsions occurring at four months and a half of pregnancy and accompanied by hemiplegia. There was no renal incompetency. The fits had been very persistent. Trinitrine was very efficacious in the first instance, but the fits recurred three weeks later and it then proved of no value. Bromides were then attended with success. The hemiplegia was transitory. Gestation was now proceeding without disturbance of health and had advanced to seven months. An adjourned discussion followed the presidential address on the Wants of the General Practitioner.

BOOKS ETC. RECEIVED.

- BAILLIÈRE, TINDALL, & COX, King William-street, Strand, London.
A manual of Veterinary Therapeutics and Pharmacology. By E. Wallis Hume, F.R.C.V.S. 1895. pp. 560. Price 10s. 6d.
CHATTO & WINDUS, Piccadilly, London.
Herbert Pry's Royal Guide to the London Charities. Edited by John Lane. Thirty-first Annual Edition. 1894. Price 1s. 6d.

Infant Feeding by Artificial Means. By S. H. Sadler. Illustrated. 1894. pp. 243. Price 6s.
Spinal Curvature and Awkward Deportment: their Causes and Prevention in Children. By Dr. G. Müller, Berlin. English edition edited by R. Greene, F.R.C.P. Edin. Illustrated. 1894. pp. 88. Price 2s. 6d.
TREKAT, E. B., Cooper Union, New York.
A System of Legal Medicine. By A. McLane Hamilton, M.D., L. Godkin, and others. Illustrated. Vol. ii. 1894. pp. 738.

WILLIAMS & NORGATE, Henrietta-street, Covent Garden, London.
 Leitfaden der Gerichtlichen Medicin. Von Dr. K. S. Seydel. 1895.
 pp. 286.
 Monatschrift für Geburtshülfe und Gynäkologie. Von Professor
 Dr. A. Martin und Professor Dr. M. Sänger. Januar. 1895.
 pp. 96.

Fires in London: printed by the Eastern Morning News Company, Whitefriargate, Hull.—Intestinal Anastomosis, with the report of a Case; by F. H. Wiggan, M.D.: reprint from New York Medical Journal, December, 1894 (D. Appleton & Co., New York).—The Report of the Committee of the Finsbury Dispensary for the Year 1893.—Cystic Gout, with Cases in Practice; by A. B. Deynard, M.D., New York: reprint from the Medical and Surgical Reporter, June, 1893.—Surgical Treatment of Tumours of the Neck; by T. H. Manley, M.D., New York: reprint from the Medical Brief, St. Louis, N.B.—The Relation of Static Disturbances of the Abdominal Viscera to Displacements of the Pelvic Organs; by J. H. Kellogg, M.D. (Modern Medicine Publishing Company, Battle Creek, Michigan, 1894).—Diary for 1895: Sanitary Record (Rider & Son, Bartholomew-close, London). The Castle Line Atlas of South Africa (Donald Currie & Co., Fenchurch-street, London, E.C.)—On the Eccentricity of Youth Leading to Crime; by L. Forbes Winslow, M.B. Camb., M.R.C.P. Lond. (John Bale & Sons, Great Titchfield-street, London, W.); price 1s., 1895.—Abdominal Surgery on the Battle-field; by N. Senn, M.D.: reprint from St. Louis Clinique, June, 1894.—Medical Officers of Schools Association: The Treatment of the Exanthemata by so-called Antiseptic Inunction; by H. G. Armstrong, M.R.C.S. (J. & A. Churchill, London, 1894); price 1s.—Revue des Sciences Médicales en France et à l'Étranger, No. 89; 15 Janvier, 1895 (G. Masson, Paris).

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

BOGER, WM. H., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer for the Fifth Sanitary District of the Liskeard Union.
BUTTS, STANLEY DE, M.D., has been appointed Anaesthetist to the Royal Bar Hospital.
DAIN, H. G., L.R.C.P. Lond., M.R.C.S., has been appointed Resident Surgical Officer to the Children's Hospital, Birmingham, vice Hickinbotham, resigned.
DAY, W.A., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer for the Kirkcaldy Sanitary District of the Guisborough Union.
FAIRFAX, H., L.S.A., has been appointed Medical Officer for the Thirteenth Sanitary District of the West Ham Union.
HAMMOND, WM., L.R.C.P., L.M., M.R.C.S., has been reappointed Medical Officer for the Sixth Sanitary District of the Liskeard Union.
HAYMAN, H. L., L.D.S., R.C.S., has been reappointed Honorary Dental Surgeon of the Clevedon Convalescent Home.
HICKINBOTHAM, J. R., L.R.C.P. Lond., M.R.C.S., has been appointed Resident Medical Officer to the Children's Hospital, Birmingham, vice Whitehouse, resigned.
ILIFFE, W., F.R.C.S. Edin., L.F.P.S., L.M. Glasg., has been reappointed Honorary Medical Officer of the Kendal Provident Dispensary.
JACKSON, E. S., M.B., C.M. Edin., has been appointed, *pro tem.*, Medical Officer for the North Sanitary District of the Lancaster Union, vice Brownlow, deceased.
JACOB, E. L., M.R.C.S., has been appointed Medical Officer to the Chertsey Urban District Council.
MACNAUL, ROBERT, M.D. Glasg., F.R.C.S. Edin., has been appointed Honorary Consulting Physician to the Suffolk General Hospital.
MACTIER, H. CARTER, M.B. B.Ch., B.A.O. Dublin, has been elected House Surgeon to the Eye Infirmary, Wolverhampton.
MARTIN, ROBERT, L.R.C.P. and S. Edin., L.S.P. and S. Edin., L.M., has been appointed Medical Assistant to the Royal Irish Constabulary, Giltford, vice J. M. Brown, resigned.
MATHISON, J. COLIN, M.B., C.M., has been appointed House Surgeon to the Royal Ear Hospital.
NIX, HERBERT W., B.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., late House Surgeon to St. Thomas's Hospital, London, has been appointed Government Resident Medical Officer, Marble Bar, Pilbarra Gold Field, Western Australia.
PARKER, W. R., M.D. Camb., M.R.C.S., L.M.R.C.P., L.M. Irel., has been reappointed Honorary Surgeon of the Kendal Provident Dispensary.
PARSONS, J., L.R.C.P., L.M., F.R.C.S. Edin., has been appointed Medical Officer for the Fourth Sanitary District of the Alton Union.
PATERSON, H. J., M.B., B.C. Camb., L.R.C.P. Lond., M.R.C.S., has been appointed Junior Assistant Anaesthetist to St. Bartholomew's Hospital, London, vice Buttar, resigned.
POOLE, W., M.B., B.C. Cantab., has been appointed Medical Officer to the British Central African Administration at Zomba, in the Shire Highlands, south of Lake Nyasa.
REES, D. V., L.R.C.P. Lond., M.R.C.S., has been appointed *pro tem.* Medical Officer for the Borough of Brecon.
RICHARDSON, W. G., M.B., B.S., F.R.C.S., has been appointed Surgical Registrar to the Royal Infirmary, Newcastle-upon-Tyne.
SHEPPARD, AMY, M.B. Lond., has been appointed Assistant Physician to the New Hospital for Women.
SKINNER, S. M.B., C.M. Aberd., M.R.C.S., has been reappointed Honorary Medical Officer of the Clevedon Convalescent Home.
STEPHENS, E., L.R.C.P., L.M. Edin., M.R.C.S., has been reappointed Medical Officer for the Chard Rural Sanitary District.
STURRIDGE, P. F., L.R.C.P., L.M. Edin., M.R.C.S., has been reappointed Surgeon of the Kendal Provident Dispensary.
TAYLOR, B. E. A., M.R.C.S., has been reappointed Surgeon of the Kendal Provident Dispensary.

TUBBY, ALFRED HERBERT, M.S. Lond., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Westminster Hospital.
TURNER, GEO., M.B. Camb., D.P.H., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Hoddesdon Urban District Council.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

CANCER HOSPITAL (Free), Fulham-road, S.W.—House Surgeon for six months. Salary at the rate of £50 per annum, with board and residence.
CENTRAL LONDON OPHTHALMIC HOSPITAL, 238A, Gray's-inn-road, W.C.—House Surgeon. Rooms, coals, and light provided.
GUEST HOSPITAL, Dudley.—Resident Medical Officer. Salary commencing at £100 per annum, increasing by £10 a year to £120 if services are satisfactory, with board, residence, and washing.
HOSPITAL FOR DISEASES OF THE THROAT, Golden-square, London, W.—Registrar and Pathologist for six months. An honorarium at the rate of 25 guineas a year.
NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Shoreditch, N.E.—Junior House Physician for six months. Board and lodging (including washing) provided.
PARISH OF RONSAV AND EIGLSHAY, Orkney—Resident Medical Officer. Salary £51 sterling per annum. Applications to Inspector of Poor, Ronsay, Orkney.
ROYAL SOUTH LONDON DISPENSARY—Surgeon in Ordinary to visit patients at their own homes in the Waterloo District. Honorarium £20 per annum. Applications at the Dispensary, St. George's-cross, S.E.
SALFORD ROYAL HOSPITAL—House Surgeon. Salary £100 per annum, with board and residence.
SUFFOLK GENERAL HOSPITAL—Honorary Assistant Medical Officer. Applications to the Secretary, Bury St. Edmunds.
UNIVERSITY OF EDINBURGH—Additional Examiners for four years. Salary £75 per annum in each case, with an allowance of £10 per annum for travelling and other expenses in the case of an Additional Examiner not living in Edinburgh or the immediate neighbourhood. Applications to the Interim Secretary, University Court, University of Edinburgh.
WIRRAL CHILDREN'S HOSPITAL, Woodchurch-road, Birkenhead.—Resident House Surgeon (lady or gentleman). Salary £50 per annum, with board, lodging on the premises, and washing.

Births, Marriages, and Deaths.

BIRTHS.

ADAMS.—On Jan. 10th, at Church-street, Slough, the wife of K. Weaver Adams, F.R.C.S., D.P.H., of a son.
BRIND.—On Jan. 13th, at Warrenbayne, Baling, W., the wife of H. Hanslow Brind, M.R.C.S., L.R.C.P., of a son.
BRYSON.—On Jan. 8th, at Osmaston-road, Derby, the wife of Leonard H. Bryson, M.B., of a son.
RICHARDS.—On Jan. 10th, at 47, Churnet-street, Collyhurst, Manchester, the wife of Arthur J. Richards, M.R.C.S., L.S.A., of a daughter.
STOCKEN.—On Jan. 16th, at Connaught-road, Harlesden, the wife of Arthur P. Stocken, L.D.S., of Endsleigh-gardens, N.W., of a son.

MARRIAGES.

CAIGER—ORR.—On Jan. 9th, at All Saints' Church, Notting-hill, by the Rev. C. E. Eckett, Rector of Woolwich, assisted by the Rev. Canon Trench, Vicar of All Saints', Frederick Forri Caiger, M.D. Lond., only son of F. H. Caiger, of 31, Arundel-gardens, W., to Madeline, youngest daughter of the late Alexander Orr, of Melbourne, Australia.
HEATON—BARNES.—On Jan. 15th, at St. Mary's, Harrow-on-the-Hill, Charles J. Heaton, M.D., M.R.C.S., L.R.C.P., second son of the late Mr. Clement Heaton, of Watford, to Mary Florence Barnes, second daughter of the late Mr. William Barnes, of Birkenhead.
HEDSON—VAUGHAN MORGAN.—On Jan. 9th, at St. Mary's, The Boltons, South Kensington, Charles Elliott Leopold Barton Hedson, F.R.C.S., of Harley-street, W., to Ethel Vaughan, daughter of Septimus Vaughan Morgan, of Harrington-gardens.
RENDLE—DARLEY.—On Jan. 16th, at St. Peter's, Belsize-park, C. R. Russel Rendle, B.A. Oxon., M.R.C.S., L.R.C.P., to Edith Mary, second daughter of J. J. Darley, 3, Lancaster-road, Belsize-park.

DEATHS.

HAKK.—On Jan. 11th, at the house of his brother, Acacia-road, N.W., Thomas Gordon Hake, M.D., in his 86th year.
HARMER.—On Jan. 14th, at Redlands, Tonbridge, William Milsted Harmer, F.R.C.P.E., aged 56.
MURRAY THOMSON.—On Jan. 13th, at Victoria-road, Gipsy-hill, Murray Thomson, M.D., F.R.S.E., Fell. Univ. Calcutta, late Professor, Experimental Science, Thomason C.B. College, Roorkhee, India, aged 60.
RAWDON.—On Jan. 4th, at Sunnyside, Clifton, York, William Frederick Rawdon, M.D. Edin., of York, aged 91.
SMITH.—On Jan. 13th, at Blackfriars-road, Septimus William Smith, L.F.P.S. Glasg., of Sussex-square, Brighton, in his 63rd year.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopaedic (2 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), Gt. Northern Central (2.30 P.M.), King's College (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North West London (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY.—INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH (20, Hanover-square, W.).—7.30 P.M. Ordinary Meeting. 8 P.M. Dr. Porter (Stockport): Preventable Infantile Mortality, especially in connexion with Factory Labour. Discussion.

SOCIETY OF ARTS.—8 P.M. Prof. Silvanus P. Thompson: The Arc Light. (Cantor Lecture.)

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Frederick T. Roberts: The Combinations of Morbid Conditions of the Chest. (First Lettsomian Lecture.)

TUESDAY.—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—Mr. A. W. Mayo Robson: Varieties of Intestinal Obstruction dependent on Gall-stones, with a series of cases.

SOCIETY OF ARTS.—4.30 P.M. Dr. A. Markoff: Russian Armenia and the Prospects for British Trade.

WEDNESDAY.—HUNTERIAN SOCIETY (London Institution).—8.30 P.M. Clinical Evening. Dr. F. J. Smith: Typhoid Fever treated by the Continuous Bath (Notes).—Sir Hugh R. Beevor: Pyo-nephrosis.—Mr. J. F. Woods: Chorea treated by Hypnotism (two cases).—Mr. J. Poland: (1) Excision of Isthmus of Thyroid Gland; (2) Intracapsular Fracture of Neck of Femur in a Boy.—Dr. Hingston Fox: A Tumour for Diagnosis.—Mr. Openshaw: (1) Congenital Sacral Tumour; (2) Congenital Defect in Clavicles.

SOCIETY OF ARTS.—8 P.M. Mr. A. G. Stanton: Tea.

FRIDAY.—CLINICAL SOCIETY OF LONDON.—8.30 P.M. Dr. S. West: Two cases of Detachment of the Retina in the course of Granular Kidney. Dr. Felix Semon: A Novel Form of Malingering—Chronic Self-inflicted Ulceration of the Throat.—Dr. Pasteur: Cases illustrating the Association of Respiratory Paralysis with grave Cardio-pulmonary Symptoms in Diphtheritic Multiple Paralysis.—Dr. E. W. Goodall: An Unusual Form of Tracheal Diphtheria.—Dr. Lee Dickinson: A case of Malformation of the Heart with Hemophilia.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

TUESDAY.—ROYAL INSTITUTION.—3 P.M. Prof. Charles Stewart: The Internal Framework of Plants and Animals (II.).

CENTRAL LONDON THROAT AND EAR HOSPITAL.—4.30 P.M. Dr. Dundas Grant: The Treatment of cases of Deafness without Pain or Discharge.

WEDNESDAY.—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 P.M. Lecture by Dr. Beevor.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-sq., W.C.).—5 P.M. Dr. Morgan Dockrell: Eczema.

ROYAL INSTITUTION.—3 P.M. Mr. Lewis F. Day: Stained Glass Windows and Painted Glass (II.).

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

THE INDEX TO THE LANCET.

THE Index for the last half-year was published in our issue of Dec. 29th, which completed the second volume of the year 1894. Those of our subscribers who may wish to be supplied with loose copies can obtain the same (without extra charge) on making application to the Manager.

TESTIMONIALS TO TRADESMEN.

Edward C. Anderson, M.A., M.D. Cantab.—Our correspondent agrees with us as to the objectionableness of a testimonial he gave to a miller as to the quality of a certain kind of oatmeal, and explains to us that it was meant to be used only among others, and not separately. This condition has been disregarded by the miller, and Dr. Anderson has very properly withdrawn his permission for use of the testimonial in any form. He is to be commended for doing so.

Struggles.—Applications for the appointment of prison surgeon should be made to the Prison Commissioners at the Home Office, Whitehall, S.W. (the Secretary is Col. M. Clare Garsia), for English appointments, and candidates are selected on their merits. Medical officers in Scotland and Ireland are, we believe, appointed by the same department, but are under separate regulations. The Secretary for the Colonies, the Marquis of Ripon, appoints the surgeons and assistant surgeons to the convict prisons abroad. The secretaries of the different Government bodies will probably answer all inquiries.

Mr. B. was entitled to more consideration than he received. He should state his grievance to Mr. T. If possible he should see him and talk the subject over. Professional relations with a brother in a neighbouring village should not be broken off without first giving him an opportunity of answering any complaint.

Dartos.—If our correspondent will ask us particular questions we may be able to furnish him with the help he requires. We are not aware of any book containing the information.

Mrs. R. (Dulwich) is informed that we do not recommend individual practitioners or any general use of the practice to which she refers.

A QUERY.

To the Editors of THE LANCET.

SIRS,—A lady aged forty-six has consulted me for an alleged fibroid in the posterior wall of the uterus. She was seen ten months ago by two medical practitioners (one of whom is an M.D. and M.R.C.P. of London and the other a F.R.C.S. of London), who examined her per rectum and pronounced that she had a fibroid tumour of the size of a chestnut. I have made a careful vaginal examination and can find no such growth. She has had irregular hamorrhages since she was forty, which have been absent during the last eight months. She has pressed me for my opinion of the case, and I have reluctantly had to tell her that her two medical attendants were mistaken in their diagnosis. I based my decision on the fact that the hamorrhages came on irrespectively of menstruation and on the impossibility of a fibroid completely disappearing in so short a time. Is this decision correct?

Is it not more probable that the hæmorrhages were due to the onset of the climacteric? An expression of opinion on this case will greatly oblige.

I am, Sirs, yours truly,

CONSULTANT.

Jan. 12th, 1895.

* As regards the hæmorrhage, it seems most probable that it was due, as our correspondent suggests, to the approach of the menopause. As to the question whether the two gentlemen who examined and found a fibroid the size of a chestnut were mistaken, or whether, on the other hand, our correspondent, who failed to find it ten months later, was mistaken, it is impossible for us to decide. Many good men not in special practice frequently make mistakes about physical signs concerning the uterus where there is something much more definite than a growth the size of a chestnut. We would remind our correspondent that it not rarely happens, even when the uterus is sufficiently enlarged by fibroids to form a tumour in the hypogastric region, that there is no unusual hæmorrhage.—*Ed. L.*

AN INQUIRY.

To the Editors of THE LANCET.

Sirs,—On the night of the 7th inst. I was called to see a child which had a sore throat and a slight rash, but presented no symptoms of malignant scarlet fever. It suffered from incessant vomiting and purging all night, and died suddenly next morning, after an illness lasting only twenty-four hours. A post-mortem examination revealed only gastro-enteritis. It was later found that sewer air could make its way through a hole in one corner of the room where the child lay. Was the death due to scarlet fever or to poisoning by sewer air? In death caused by sewer air are there any pathognomonic post-mortem signs? and, if so, where are they described? Would bacteriological examination be decisive?

I am, Sirs, yours truly,

REGULAR SUBSCRIBER.

Jan. 17th, 1895.

Enquirer.—It is courteous and proper, when a patient changes his medical man, to intimate the same to his previous adviser. If he fails to do so, or refuses, the practitioner called in is not under obligation to communicate the fact, but it might easily be a friendly and neighbourly thing to do so. A patient changing his adviser, and known to be doing so, should be informed by the new adviser of his duty.

C. W. L. is informed that his letter is receiving every attention. When we decide whether we can do anything practical and what we shall do we will communicate with our correspondent. In the meantime nothing would be gained by printing our correspondent's letter.

H. E. B. (Cricklewood).—We never recommend individual practitioners; but our correspondent's medical man would be able to inform him where he can obtain the best practical advice.

A QUESTION OF ETIQUETTE.

To the Editors of THE LANCET.

Sirs,—D. was out shooting with B., when he was accidentally shot in the foot. C. (the nearest surgeon) was sent for; also M. (B.'s medical attendant); also X. (D.'s medical attendant), the latter fifteen miles off. C. waited, and after consultation M. left, having an appointment. C. remained, and assisted at a Syme's amputation. X. carried on the case, but accepted C.'s offer to act in emergency. C. heard nothing more of the case for seven days, when B. wrote and asked him to sit up all night, as D. was very ill, and X. had left for home, and M. was not able to come. C. then found that reamputation had been carried out; so at first refused, but at B.'s request stayed in the house all night, but did not see D. 1. Was C. correct in refusing to see D. under the circumstances? 2. Was X. correct in reamputating without asking C. to be present?

I am, Sirs, yours faithfully,

DOUBTFUL.

Jan. 14th, 1895.

* The facts are too imperfectly stated to enable us to express a very confident judgment. It would have been courteous for X. to have consulted C. before reamputating, seeing that C. had been associated with him in the treatment of the case. C. acted kindly in staying in the house of the patient in place of M., and doubtless would have risen to the magnanimity of seeing the patient had need arisen.—*Ed. L.*

QUALIFICATIONS AND TITLES.

To the Editors of THE LANCET.

Sirs,—I should be much obliged if you would kindly inform me through the columns of THE LANCET if there is any advantage in an L.R.C.P.I. possessing the L.M. as well. The latter diploma states that the candidate is "fully qualified" to practise therein. He is examined in midwifery for the L.R.C.P.; and does not this examination "fully" qualify him for the practice of midwifery? Would you also kindly suggest a suitable inscription for the doorplate of a practitioner who is L.R.C.P., L.M. (Irel.)?

I am, Sirs, yours faithfully,

OBSTETRICS.

Jan. 7th, 1895.

* A practitioner already registered would not derive any advantage from the additional degree. The proper style for our correspondent's doorplate is "Mr."—*Ed. L.*

THE HYDERABAD METHOD OF ADMINISTERING CHLOROFORM.

To the Editors of THE LANCET.

Sirs,—During a recent visit to Hyderabad, Deccan, I had the pleasure of seeing chloroform administered on several occasions according to the method adopted by Surgeon-Lieutenant-Colonel Lawrie, the inhalations being conducted under his personal supervision. The routine of administration is briefly as follows:—The patient walks, if possible, or is carried into the operating theatre and lies down on the table with the chest uncovered. Four students then undertake the management of the patient. The first student announces so that every one present may hear all the phenomena and the exact time of occurrence from the beginning of the administration until the patient recovers consciousness, the amount of chloroform given, the variations of pulse respiration, &c., all being noted. The second student writes down the same on specially arranged forms. The third student stands on the administrator's right with a drachm measure-glass and a bottle of chloroform, and measures it out as required. The fourth student is the administrator. He takes a cone made of canvas, stiffened on either side with a thin piece of cane. In the apex of the cone is placed a piece of clean cotton-wool, on which is poured one drachm of chloroform. The cone is then held over the nose and mouth, but not in close apposition. Drachm doses are poured on the wool every minute until struggling commences, the dose is then reduced to half a drachm every forty-five seconds. Anaesthesia being complete, the smallest amount possible to keep the patient under is administered. If signs of irregular breathing appear after the patient has become unconscious the inhalation of chloroform is withheld until it becomes regular, artificial respiration being performed if necessary. Respiration is what they look to for a warning of approaching danger, and not the pulse. Dr. Lawrie is present during the whole time, correcting any inaccuracies in recording phenomena. The patient is not removed from the operating table until he shows signs of return to consciousness.

As a large number of your readers had not an opportunity of seeing chloroform administered by some of Dr. Lawrie's pupils in London last summer, I thought this brief account might be interesting to them.

I am, Sirs, yours truly,

CLARENCE READ.

Jan. 4th, 1895.

"ON THE TREATMENT OF GLEET BY THE URETHROSCOPE."

To the Editors of THE LANCET.

Sirs,—In reference to the distribution of marked copies of the *Medical Week* to various clubs, to which your correspondent of last week calls attention, I am requested by Dr. de Maurans, the editor-in-chief, to state that no copies were sent from the office to other than subscribers, the Isthmian Club not being among the number.

I am, Sirs, yours faithfully,

ALFRED S. GUBB, M.D. Paris.

Rue de l'Abbé-de-l'Épée, Paris, Jan. 15th, 1895.

E. T. J.—The only institutions which receive male epileptics are the Home for Epileptics, Maghull, Lancashire, and the Colony at Chalfont founded by the National Society for the Employment of Epileptics, whose offices are at 12, Buckingham-street, Strand. Our correspondent should address the secretaries of those institutions; but neither receives patients if there is any marked mental defect.

A Correspondent writing from Tremont-terrace, Leeds, is informed that we never give medical advice. His annoying ailment is generally susceptible of relief or cure, and we advise him to consult his regular medical practitioner, who will, if the condition remains obstinate, recommend him how to obtain further advice.

Mr. W. L. Jones.—The physical examination for the different medical services is much the same. It will greatly depend upon the number of teeth lost or decayed, the age of the individual, his present state of nutrition, and the estimated effect which this defect would probably have upon mastication and digestion.

Nursing Sister.—The India Office.

During the week marked copies of the following newspapers

have been received:—Derbyshire Times, Leicester Post, United Service Gazette, Whitehall Review, La Presse (Paris), Sussex Daily News, Bristol Times, Manchester Guardian, Windsor Gazette, Newcastle Chronicle, St. Austel Star, Swansea Journal, Glasgow Evening News, Birmingham Post, Huddersfield Daily Chronicle, Scarborough Post, Cape Times, Liverpool Mercury, Dunstable Borough Gazette, Somerset County Mail, Pullman's Weekly News, Witney Gazette, Eccle Government Chronicle, Sanitary Record, West Middlesex Standard, Brixton Free Press, Hertfordshire Mercury, Grimsby News, Weekly Free Press and Aberdeen Herald, City Press, Reading Mercury, Midland Weekly Herald, Builder, Pioneer Mail, Scotsman, Architect, Swindon Advertiser, Leeds Mercury, Times of India, Barnsley Independent, Grays Standard, Surrey Advertiser, West Middlesex Advertiser, Local Government Journal, Havick Express, Alloa Advertiser, Guy's Hospital Gazette, Burton Chronicle, Hertford Times, Loughborough Examiner, Bristol Mercury, Building News, Yorkshire Post, Kent and Sussex Courier, Tunbridge Wells Gazette, Runcorn Guardian, Brecon and Radnor Express, Berwick Recorder, Grantham Journal, Jockmontwyke Reporter, St. Bartholomew's Journal, The Porcupine, Preston Herald, &c., &c.

Communications, Letters &c. have been received from—

Lettsomian Lectures

ON THE

COMBINATIONS OF MORBID CONDITIONS OF THE CHEST.

*Delivered at the Medical Society of London on Jan. 21st, 1895,*By FREDERICK T. ROBERTS, M.D.,
F.R.C.P. LOND.,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS AT UNIVERSITY COLLEGE; PHYSICIAN AND PROFESSOR OF CLINICAL MEDICINE AT UNIVERSITY COLLEGE HOSPITAL; CONSULTING PHYSICIAN TO THE BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

LECTURE I.

MR. PRESIDENT AND GENTLEMEN, — When, having accepted the honourable and responsible position of Lettsomian lecturer, I had to face the trying question of my subject, the one which I have chosen kept forcing itself upon my attention, until at last an irresistible impulse took hold of me to attempt to grapple with it. I am afraid that to many here present the title "Combinations of Morbid Conditions of the Chest" suggests a very uninteresting discussion. The subject certainly does not appeal to that craving for novelty which is so characteristic of the age, and from which even the medical profession is by no means free. I therefore feel it necessary to give two or three reasons for my selection. I take it for granted that the frequency and gravity of cases of chest disease, in every kind of practice and in every grade of social life, must be familiar to all. Not only do they contribute to an appalling extent to the general mortality, but the sufferings and miseries which they inflict upon humanity are beyond all calculation. I have had opportunities of observing and studying these cases on a somewhat large scale, and with increasing experience I have become more and more impressed with the importance of studying the combinations in which morbid conditions of the chest present themselves in individual instances in actual practice. Of course, such combinations are well known to those who have had a similar experience, but my observation has forced me to the conclusion that they are by no means so generally recognised and appreciated as they ought to be, while certain conditions which in my opinion are of real consequence are often entirely ignored. It is too much the custom to look upon thoracic cases as if they were cut-and-dried examples of individual diseases, as described in text-books and lectures, with which we associate distinctive names; to apply to them terms and expressions which have in reality no definite significance; or to fix upon some one prominent physical change or condition, to the exclusion and neglect of all others which may happen to be present. Even special treatises on chest diseases discuss the various affections in the main as if they were entirely separate and independent. Another reason which has influenced me in the choice of my subject is that it gives me the opportunity of uttering an emphatic protest against the absurd development of specialism in relation to this region which at the present day is working so much mischief, as well as against the narrow conceptions so widely entertained with regard to certain prominent modern theories and doctrines, in themselves of the highest importance, and the vagaries in so-called "scientific therapeutics" resulting therefrom. Chest specialism certainly deserves recognition quite as much as the majority of specialities, but only within due and rational limits. Anyone who knows anything about the important structures which occupy this cavity must recognise the necessity of being always prepared to study them, from a pathological and clinical point of view, not only in their more immediate connexions, but also in their relations to associated structures outside the thorax, and to other organs and systems of the body. And, further, the practice of dealing with each thoracic organ as if it were entirely separate and distinct, or, still more, of making a speciality of particular complaints, is both dangerous and absurd.

Permit me now to offer a few words of explanation in relation to the title which I have adopted for these lectures. In the first place, the word "chest" is used in a comprehensive sense, and is intended to include all structures which are directly associated with this region. These may be conveniently arranged in the following way: (1) the chest

walls, including the superficial and muscular tissues, as well as the bony and cartilaginous framework; (2) the diaphragm, a structure as a rule entirely forgotten and ignored; (3) the lungs and pleura, with the trachea and its primary bronchial divisions; (4) the heart and pericardium, with the great vessels, both arteries and veins; (5) the less prominent contents of the mediastinum, including chiefly the oesophagus, absorbent glands, thoracic duct, and certain important nerves, but not forgetting also the thymus gland, and the mediastinal cellular tissue; and (6) the abdominal viscera which are contiguous to the diaphragm, and which, though not actually contained in the thoracic cavity, come normally more or less within the area covered by the ribs, especially the liver, stomach, and spleen.

Under the expression "morbid conditions" I include both functional disorders and organic changes. I am well aware that not a few object to the word "functional" as applied to any morbid state whatsoever, but I must pass over this question, and will only say that, in relation to the subject with which we are now concerned, disturbances affecting the important functions immediately connected with the thoracic structures, usually of a temporary nature, not uncommonly occupy a prominent place. With regard to organic changes, these are of various kinds, but, speaking generally, they may be conveniently grouped as follows: (1) those which are not injurious in themselves, but are important on account of the physical effects which they produce (and this class of lesions are often the remains of some previous acute or active disease); (2) permanent structural changes impairing the functions of organs; (3) more or less acute diseases or morbid conditions which are temporary, inasmuch as if they do not prove fatal within a limited period they as a rule clear up or disappear when their determining causes are removed; (4) changes which are grave in themselves, either from the immediate danger due to some serious lesion or from their essentially fatal tendency, or being of a destructive type or of a septic and infectious nature, or because they become the occasion of, or predispose to, dangerous secondary lesions; and (5) morbid conditions, often obvious enough and persistent, but which in reality are of a curative or compensatory character—these may be quite harmless, or even beneficial and helpful, but not uncommonly they are accompanied with impairment of function, owing to the permanent damage done to the affected organ. I have next to deal with the title of my subject as a whole, and to speak of the combinations of morbid conditions of the chest in the comprehensive sense just referred to. A large proportion of chest cases, as they come under our notice in living patients, to say nothing of undetected changes which we find post mortem, present various combinations of morbid conditions, for which, as medical practitioners, we have to be constantly on the look-out, otherwise we are ever in danger of going astray in our diagnosis. Many of these associated conditions can be readily and fully appreciated and understood by any properly trained clinical observer; but sometimes they become so numerous and complicated that it may be very difficult or even impossible to determine the exact state of things. A point which calls for notice here is that some cases become important, or even serious, simply because they present a number of conditions in combination, not one of which would in itself be of any material consequence.

I have classified under certain groups the chest conditions and their combinations which are likely to be met with, in the hope that such an arrangement may be practically useful for future reference, and as a basis for the study of individual cases; but I do not pretend in the time at my command to enter into details, or to describe the numerous combinations of chest conditions which I have personally observed. My object is merely to generalise, illustrating my remarks by the occasional mention of some specially instructive case. I have no intention whatever of giving a lengthy description of any case, nor do I propose to inflict upon you any statistics. Having completed this—the most important—part of my subject, I desire afterwards to indicate briefly some clinical lessons which its consideration suggests, especially in relation to the investigation of chest cases; and, in conclusion, to submit a few general remarks as to its bearing upon their diagnosis, prognosis, and treatment.

SYNOPSIS

General Classification of Morbid Conditions of the Chest and their Combinations.

- I. Conditions of the chest walls and diaphragm.
- II. Slight or indefinite intra-thoracic changes.

D

- III. Combinations of changes belonging to Nos. I. and II.
- IV. Secondary effects of certain intra-thoracic physical conditions.
- V. Combinations of chronic diseases or their remainrs.
- VI. Combinations in acute cases.
- VII. Combinations due to accidental lesions or complications, usually sudden.
- VIII. Combinations associated with sudden or acute disorders of function, temporary or paroxysmal.
- IX. Combined conditions originating from the abdomen.

In the first instance I submit for your consideration a table which presents a general outline or sketch of the course which I propose to take in discussing the part of my subject with which we are now concerned, and this may afford some comprehensive idea as to the classes of chest cases in which we are likely to meet with various combinations of morbid conditions. Without further comment I proceed to discuss the several groups mentioned.

I.—CONDITIONS OF THE CHEST WALLS AND DIAPHRAGM.

That great clinical teacher, Sir William Jenner, used to impress upon us as students some important facts about the chest walls; but my observation compels me to say that nowadays they are not regarded as of much account. I suppose that anyone who makes the slightest pretension to being a clinical observer could scarcely fail to be attracted by such striking and prominent conditions as subcutaneous oedema or emphysema, the presence of a growth, or an extreme deformity; but I fear that other less attractive changes are seldom thought of, though in reality they not uncommonly add seriously to the sufferings and difficulties of the patient. It would be altogether beyond the province of my subject to attempt to discuss in detail the numerous morbid conditions of the chest walls and diaphragm; but I wish to point out emphatically that these structures, and the former especially, are always well worthy of consideration when dealing with thoracic cases. The skin of the chest sometimes, less commonly now than formerly, shows the marks of some energetic local treatment by cupping, leeching, &c., which suggest that the patient had an acute intra-thoracic inflammatory attack at some time or other, likely to leave behind permanent changes, of the existence of which in the particular case it is desirable for us to be aware, but which we cannot definitely detect. Further, a scar may draw attention to a former operation for pleural effusion or an empyema. As illustrations of the association of superficial conditions with those within the chest the following may be mentioned. Painful sensations in many cases of internal disease of different kinds are certainly connected with the superficial structures, whether neuralgic, neuritic, myalgic, "referred," or by whatever other name they may be called. Cutaneous hyperæsthesia is also sometimes very pronounced. Spasm of the muscles of the chest walls may likewise be associated with some internal disorders. It is well known that pleurisy may be associated with herpes zoster, or with an extensive burn or scald of the thorax, as well as with injury, and the results remain in the form of adhesions. Certain states of the chest walls may occasion a disturbance of the normal internal arrangements, as in the case of a cleft sternum, or when a ruptured muscle allows a hernia of the lung to take place. Having given these general illustrations, I cannot resist making a few remarks upon certain individual conditions connected with the chest walls, simple enough in themselves, and of very frequent occurrence in association with internal diseases, but which, from their very frequency and simplicity, are constantly overlooked and neglected in practice.

Wasting of the superficial tissues and muscles.—Wasting of the soft structures of the chest walls, and especially of the muscles, is a very common factor in diseases of this region, being noticed most conspicuously, but by no means solely, in cases of phthisis. Its local effects ought always to be fully taken into consideration, and it must not be merely regarded as a part of the general wasting. I do not suppose that in its minor degrees it contributes appreciably to the troubles of the patient, but marked emaciation may add materially to the difficulties of the acts of breathing, coughing, and expectoration, contributing but too obviously to the distress and inefficiency of these acts, while under certain circumstances it may become an immediate source of danger.

Softness of the ribs.—This condition is natural during early life, but its association with different affections involving the lungs must always be kept in mind. Any obstruction to

the passage of air through the main air tube, or even a slight bronchial catarrh, and still more a serious bronchitis or pneumonia, becomes under the circumstances unusually important, and its possible effects must be estimated accordingly. Softness of the ribs as a morbid state is very often met with in children as a consequence of rickets; in adults the condition is only of very rare occurrence in connexion with osteomalacia.

Rigidity of the chest walls.—The changes which take place in the framework of the thorax, leading to undue firmness or rigidity, with consequent interference with its mobility, amounting in extreme cases to absolute fixation, are of common occurrence under a variety of circumstances, and are not infrequently of decided consequence. I make it an invariable rule to look for them when dealing with any chest case, at any rate in subjects approaching or beyond adult life, and to endeavour to estimate their effects in relation to certain physical signs and symptoms, and yet my experience compels me to say that they seldom attract the notice they deserve, even when of a very pronounced character. The changes which produce the rigidity are well known, consisting of undue calcification of the ribs and sternum, with incomplete ossification or calcification of the costal cartilages; while changes also take place in the joints, which ultimately lead to their more or less complete ankylosis. Of course, these changes develop naturally with advancing age, and there is at any rate no excuse for overlooking them in old people. But the more or less "rigid chest" is quite frequently met with in individuals who have not yet reached middle life; and in the ordinary run of practice it is astonishing how often it is revealed in the examination of even young subjects. Under these circumstances it is generally, but not always, obviously traceable to the effects of hard physical work, excessive indulgence in athletic and allied exercises, injudicious training for the public services, and like causes. The changes which lead to rigidity of the chest walls may be but a part of the entire case, developing along with other morbid processes which are taking place within the thorax, or being in some instances probably the secondary result of these processes. The effects of a rigid chest are easily understood, and it is readily detected by physical examination. Speaking generally, its most obvious consequences are that it interferes more or less seriously with the respiratory movements—expiratory as well as inspiratory—the thoracic walls becoming in extreme cases absolutely fixed and immobile; and that it prevents their expansion under certain circumstances. Now in itself this condition may not lead to any obvious disturbance; but let it be associated with internal thoracic diseases of different kinds, and its effects become at once apparent, especially if the thorax happens to be of small capacity. It is remarkable, for instance, how it adds to the severity of the symptoms of, it may be, only a slight bronchial catarrh; while it becomes in itself a real source of danger when any pronounced acute inflammatory affection develops within the chest, and especially if it should lead to some definite physical condition which encroaches upon the thoracic cavity, such as pleuritic or pericardial effusion. Again, rigidity of the walls may greatly limit or actually prevent the distension or expansion of the chest, which should be the natural result of certain intra-thoracic conditions, and may thus be of serious consequence. The most striking illustration of this statement is afforded by a certain class of emphysematous cases. I need scarcely say that extensive vesicular pulmonary emphysema tends to cause general enlargement of the thorax, which up to a certain point may be regarded as a tendency in this region to accommodate itself to circumstances. But when this condition develops for the first time late in life, or in a person whose thorax has become prematurely rigid, such enlargement is either entirely prevented, or it is so much curtailed and modified in its details, that it in no respect falls in with the ordinary description of an emphysematous chest. Moreover, under these circumstances the symptoms are obviously likely to be much more pronounced and troublesome than they otherwise would be. I have also met with cases of greatly enlarged heart in which the rigid chest walls would not yield, and consequently no cardiac bulging could be produced, so that the organ was obliged to encroach upon the thoracic space and to interfere with the other contents of the thorax, as well as with the diaphragm, the symptoms being accordingly much more severe than they would otherwise have been.

Abnormalities in shape and capacity: chest deformities.—The conditions which come under this heading are important in themselves, as well as extremely interesting in relation to

chest affections. A chest of contracted dimensions and small capacity ought to be regarded as a "morbidity condition," whether it is the outcome of a natural delicacy of frame or of a want of proper development in early life, or is the result of internal disease. When primary, it is necessarily associated with a state of things within the thorax which undoubtedly predisposes to a certain class of diseases, and in course of time we are confronted with the manifestations of the combined conditions in many of the cases of phthisis which we meet with. In the opposite direction, a chest that is over-distended from any cause is in itself actually morbid, and is not merely an indication of some internal disease, a fact of which the athletes of the present day may well take note. The different unilateral and local changes in the shape and size of the thorax that so frequently come before us must also not be regarded as mere "physical signs" of various conditions, inasmuch as they themselves frequently constitute a part of the entire group of morbid changes with which we are concerned. It is, however, possible to attach an undue importance to slight changes of this kind. It is well not to jump to the conclusion that an intra-clavicular depression necessarily means phthisis, or that the bending forwards of a rib cartilage is the prominent sign of an aneurysm. Pronounced deformities of the chest, especially those resulting from spinal disease, are often very sad and trying, if only on account of the immediate effects of the deformity upon the contents of the thorax; when, in addition, the walls become rigid, while various acute or chronic intra-thoracic diseases supervene, which are by no means necessarily the direct outcome of the deformity, the entire complication is often very perplexing, while the symptoms are proportionately grave, and sooner or later the termination must inevitably be fatal.

Conditions affecting the diaphragm.—Different conditions of the diaphragm may follow upon—

- (a) Functional disorders; spasm; paralysis.
- (b) Mechanical embarrassment or displacement.
- (c) Acute inflammation; diaphragmatic pleurisy.
- (d) Adhesion to neighbouring structures.
- (e) Chronic structural changes: atrophy; fatty degeneration; fibroid changes.
- (f) Rupture, perforation, or congenital deficiency.

I now only indicate in a general way the morbid conditions which may affect the diaphragm, and remind you that one or other of these conditions is in not a few instances an important factor in connexion with intra-thoracic diseases, of which I may give some illustrations later, and your own experience will probably bring to your remembrance individual cases exemplifying this point.

II.—SLIGHT OR INDEFINITE INTRA-THORACIC CHANGES.

Under this head I wish to draw attention very briefly to certain changes which take place within the chest, and I term them "indefinite" because, though of very common occurrence, and in many instances easily made out by skilled investigation, they give rise to no evident symptoms, and, indeed, can often only be detected by methodical and careful physical examination. In some cases, moreover, their presence, though it may be reasonably suspected, is rather a matter of inference or guesswork than of actual demonstration. The conditions to which I allude are: 1. Localised pleuritic or possibly pericardial adhesions. 2. Ill-defined changes in the pulmonary structures, such as senile atrophy, lesser degrees of over-distension of the lungs or even of true vesicular emphysema, commencing degeneration, impairing the pulmonary elasticity and expiratory force, and limited fibrotic changes, the remains of a cured phthisis or other past lesion. 3. The lesser degrees of atheromatous degeneration of the thoracic aorta and its main branches. 4. Atrophy or early degenerative changes affecting the heart walls, or infiltration of its muscular tissue with fat. I may note, by the way, that the viscera and other structures are in exceptional instances congenitally transposed, and this is a condition of an indefinite nature to be borne in mind as a possible accompaniment of pronounced intra-thoracic disease, especially in relation to the heart. Most of the changes to which I have referred usually come on gradually and imperceptibly as the natural result of the wear and tear of life, or of other causes to which I have alluded when speaking of the chest walls. Some of them, however, may be the remains of a past illness, of which the patient may be aware or of which he has no distinct remembrance. Intra-thoracic adhesions, even of considerable extent, are, it is well known, not uncommonly found post mortem, the origin of which cannot be traced and the existence of which was not

recognised during life. At the same time, I venture to assert that many such adhesions can be easily detected by proper examination, if there has been an opportunity for carrying it out in the living patient.

III.—COMBINATIONS OF CHANGES BELONGING TO I. AND II.

Although I have dwelt so long upon conditions which may appear to be of minor importance, I must still ask your attention for a moment to a distinct group of cases, of which I have seen numerous examples, and which are characterised by the presence of certain of these conditions in combination, affecting both the walls and the contents of the thorax, and therefore assuming a degree of importance which they would not otherwise possess. In these cases the superficial structures are more or less wasted—it may be considerably; the chest walls are obviously rigid; localised pleuritic adhesions can be made out—it may be in several spots; there are no gross lesions to be detected in the lungs, but these organs are evidently wanting in normal elasticity and tending towards degeneration, perhaps also exhibiting limited areas of emphysema, or there is a suspicion of a fibrotic change here and there; sometimes there are indications of commencing atheroma of the aorta, or the heart is feeble in its action and is probably of actually small size. Now I maintain that cases of this kind ought to be definitely recognised, though it is difficult or even impossible to apply to them any particular designation. They do not exactly belong to the chronic emphysematous or the phthisical group, and they can only be included under that somewhat vague category known as a "weak chest." The patients who suffer from this combination of changes are fully aware of their existence, for at any rate they affect their breathing powers considerably, while they render them extremely susceptible to the effects of even a slight cause likely to act injuriously upon the respiratory organs. Still, so long as they keep quiet and consent, and are able, to remain in a comfortable house or room during the colder seasons of the year, or to reside in some more genial and suitable climate than ours, they get on very well. Let them, however, have even the slightest bronchial catarrh, or, still more, a pronounced acute bronchitis or a pneumonic attack, and their troubles increase at once in a marked degree, while the danger to life also becomes for obvious reasons very serious, quite out of proportion to the acute illness in itself, and I know of few more anxious combinations of conditions to deal with in practice.

IV.—SECONDARY EFFECTS OF CERTAIN INTRA-THORACIC PHYSICAL CONDITIONS.

Here I merely wish to point out that given a particular physical condition within the chest, others are likely, or in many instances certain, to be produced by it as secondary consequences, varying in their nature and degree within well-known limits. Hence it happens that the case presents itself as a more or less complex one, there being a combination of morbid conditions which it is incumbent upon us to recognise, at the same time endeavouring to determine and estimate how far each contributes to the sum total of the clinical phenomena observed. It is too much the custom to look upon these secondary effects as mere "physical signs" of the primary condition, their real importance in themselves being overlooked, or at any rate not adequately appreciated. As illustrations of the more prominent conditions which originate this more or less complicated state of things—to some of which I shall have again to refer—I may mention a large fluid or gaseous accumulation in the pleural cavity, or a much thickened and extensively adherent pleura; pericardial effusion; marked general emphysema, and an intra-thoracic tumour of any description, whether aneurysmal, solid, or of other kinds. I may draw attention to one special point in this connexion—namely, that when from any cause the action of either lung is extensively interfered with, the opposite one almost necessarily undergoes compensatory enlargement, and the combination may be easily misunderstood unless due care be exercised.

V.—COMBINATIONS OF CHRONIC DISEASES OR THEIR REMAINS.

In speaking of the remains of chronic diseases I refer to what are truly morbid changes, not active, and often the manifestations of the arrest of destructive or other injurious processes, and of an attempt at repair of the damage. It will be observed that in some groups the changes are practically confined to one particular structure or class of

structures; in others two or more are involved, but in a large proportion of these cases the connexion between the several lesions is sufficiently obvious and intelligible, if properly studied. Sometimes, however, the morbid changes are quite independent of each other, or they become so complicated that it is very difficult or even impossible to trace any distinct relation between them. It would obviously be impossible in the time at my command to discuss the several conditions at any length, and my observations are meant to be merely of a general character.

A.—Respiratory Apparatus.

There are many chronic chest cases in which the morbid conditions, though more or less complex, are practically confined to the respiratory apparatus, and these cases I now proceed to consider.

Pleuritis.—There is a definite class of chronic chest cases in which we have practically to deal with prominent morbid states of the pleura and their immediate consequences. They have either started in a well marked attack of pleurisy with effusion or have followed an empyema which has opened into the lung or been operated upon, or they have sometimes developed slowly and imperceptibly. In exceptional instances they appear to have originated in a limited pneumothorax, which has probably been associated with phthisis, the progress of this disease having been checked by the pleural lesions. The large majority of chronic pleuritic cases are simple enough, but in some instances the conditions are decidedly complicated, and we may meet with various combinations of adhesions, great thickening, localised collections of fluid, or possibly even the remains of a pneumothorax or pyo-pneumothorax. Nor must I forget to note here that the pleura may be the special seat of an extensive tuberculous or malignant infiltration, which still further complicates matters. The important practical lesson for us is, that when brought into contact with what is obviously a chronic pleuritic case, we must not jump to the conclusion that we have to deal simply with an effusion.

Pulmonary and air tubes.—Of course, there is no definite line of demarcation between the bronchial ramifications and the other tissues which enter into the construction of the lungs, and it is a familiar fact that they are all more or less implicated in a large number of cases. Under this head, however, it will be convenient to notice also certain lesions affecting the main air passage or its primary bronchial divisions which are liable to be met with in connexion with some lung diseases. The following subdivisions indicate fairly clearly the aspects under which the large majority of chronic pulmonary cases come before us in practice, and I propose to say a few words about each.

(a) **Phthisical.**—Many of the laity talk glibly about microbes, tubercle bacilli, tuberculous granulations, and the like, and are ever on the look-out for the latest "cure" for this disease without seeming to realise in the least that there are any actual lesions, pulmonary or other, and even when the chest and its contents have become a total wreck their eyes are not opened to the absurdity of their notions, and they will fly to any quack who promises a cure. Of course, I do not suggest that these ideas are held by any medical man of average education, but I must say that what one reads and hears indicates rather an undue fondness for bacilli, and often reveals a want of due appreciation of the actual morbid changes which ordinarily characterise phthisical cases, especially as regards their extent and combinations. It is not my business on the present occasion to discuss the pathology of phthisis or to describe its lesions; nor do I wish to minimise in the smallest degree the importance of the bacillary doctrine in relation to this complaint. My subject, however, compels me to point out that the changes in the lungs themselves, setting aside other thoracic structures, are definite enough and well understood, are often of a pronounced nature, and in cases of some duration are sure to be more or less combined, ultimately not uncommonly culminating in a highly complicated state of things. As the evidence and results of the phthisical process in these organs we have to deal with distinct areas or masses of consolidation—tuberculous, inflammatory, caseous, or mixed; miliary tubercles, diffused or in groups; softening of these structures and breaking down, leading to destruction of the pulmonary tissues; cavities in all varieties of size, shape, characters of walls and surroundings, and contents, more or less suppurative usually taking place in them; as well as with changes indicating a tendency to arrest of the disease in places, and to a reparative process, especially

the formation of a fibroid tissue, which leads to induration and contraction of the affected portion of lung, with narrowing, and it may be even ultimate closure of cavities. Then we have to recognise also, in many cases, an associated bronchitis, which contributes more or less to the expectoration; while in some instances there are definite tuberculous ulcers in the larger bronchi or the trachea. The more pronounced laryngeal complications of phthisis hardly come within the scope of my subject, as the larynx is outside the thoracic cavity, but I may point out that laryngeal symptoms are occasionally produced by the effect of phthisical changes upon intra-thoracic nerves, and these also must not be overlooked. Again, in parts of the lungs not actually phthisical, compensatory distension, or so-called emphysema, is often met with; and, further, there are vascular changes, but the only one I need specially mention is the possible development of an aneurysm on a branch of the pulmonary artery within a cavity. In that special group of cases known as "mechanical phthisis" there is the additional element of the solid foreign particles infiltrating the lung tissues. It is very important to recognise the pathological nature of the different solid materials met with in phthisical lungs, and it is quite incorrect, as well as misleading, to sum them all up under the general term "consolidation."

(b) **Emphysematous and Bronchitic.**—The term "emphysema" is used not uncommonly in a very loose fashion, to signify any abnormal pulmonary distension or accumulation of air in the lungs, whether general, unilateral, or local. I am at present concerned, however, with the real disease, in which not only are both these organs more or less enlarged and distended, but their tissues have also undergone certain structural changes, chiefly evidenced by impairment or loss of elasticity. Now this condition is very likely to be associated with a chronic bronchial catarrh or bronchitis of some kind, though there are times when the patient may be practically free from any such trouble, while it is liable to periodical exacerbations from the action of well known causes. In many instances, of course, it is the bronchitis which has been the primary disease, and it may be affirmed as a general statement that this complaint cannot persist for any length of time without producing more or less emphysema—even in early life. I have often been distressed by the pitiful sight of young subjects suffering in this way, evidently as the consequence of ignorance or neglect. In whatever manner they may have commenced a large number of the cases designated "emphysema and bronchitis" are comparatively simple; but even then we ought to try to determine certain details, as, for example, the degree of distension of the lungs, the amount and nature of the changes in their tissues, and how far their elasticity is impaired, the kind of bronchitis, with its amount and mode of distribution, and the state of the chest walls. I have already referred to the importance of rigidity of the thorax in relation to the emphysematous condition. In emphysematous and bronchitic cases the lungs occasionally become more distended than usual, owing to the escape of air from them being obstructed by the conditions of the bronchi. Under such circumstances the emphysema appears to be greater in degree and extent than it actually is, and when the obstruction is removed the lungs diminish in bulk—it may be considerably,—as evidenced by the size of the chest, while its movements also improve in proportion. With regard to the changes affecting the bronchi in the cases now under consideration, we have to bear in mind not only that there are different varieties of bronchitis, but also that the walls of these tubes are in time likely to undergo serious permanent changes, their mucous lining becoming disorganised and more or less extensive bronchial dilatation being often finally established. Bronchiectasis should more especially be remembered as a possible condition, because extensive emphysema will often completely obscure the physical signs which may be expected to reveal the presence of the dilated tubes. Plastic bronchitis is a rare variety which may be associated with a more or less emphysematous state of the lungs.

(c) **Chronic Pneumonic.**—I can only very briefly refer to the conditions which come under this heading. There are the well-known cases of chronic interstitial pneumonia, which are described under the terms "cirrhotic or fibroid lung," "fibroid phthisis," &c. These in time assume a decidedly complex character, in whatever way they may have originated. The fibroid change is limited in most cases mainly or entirely to one lung, or a portion of it, which is thus hardened and contracted, the involved structures being rendered quite useless; it is also often accompanied with the remains of

phthical cavities, and still more frequently with dilated bronchi; while unaffected areas of the same lung, as well as the opposite one, become the seat of compensatory distension, which may ultimately terminate in true emphysema. Sometimes both lungs are involved in unequal degree, or if one is not fibrotic it is frequently the seat of bronchitis. There is an exceptional class of chronic pneumonic cases which may prove very puzzling. In these one lung is absolutely solid, either throughout or over a large extent, but instead of being contracted it is more or less enlarged. The opposite lung becomes greatly distended, and also in some instances the seat of dry bronchial catarrh; so that the general aspect of the patient, as well as the prominent symptoms, may resemble closely at first sight those of an extreme case of emphysema and bronchitis, with an asthmatic tendency.

(d) Syphilitic.—Time forbids my doing more than allude to these cases. They are somewhat indefinite from a clinical point of view, though they occasionally present distinct combinations of different morbid conditions, which it may be possible to recognise during life.

(e) Mixed.—I have already given illustrations of mixed conditions in the lungs in my discussion of the specially named groups; but I have thought it desirable to designate by this term a particular class of cases in order to emphasise the fact that any of the pulmonary lesions which I have been thus far considering may be met with together in almost every conceivable variety of combination. There are two points to which I more especially wish to draw your attention in this connexion. I have heard it often stated—and it seems to be rather a prevalent idea—that emphysema and tuberculosis are antagonistic and are rarely observed together. Now, as a matter of fact, phthical changes are not at all uncommon even in markedly emphysematous lungs, while it is quite usual to find the two conditions associated together in different parts of the same organs. Under these circumstances the physical signs of the tuberculous lesions are very likely to be obscured, and we may have to rely very much on the symptoms in their diagnosis. The other point to which I must refer is the relation between phthisis and chronic bronchitis. There is a distinct class of cases in which, chronic bronchitis having existed in a more or less pronounced form for a variable period, tuberculous changes ultimately supervene, which are easily explained on the bacillary theory, and the clinical phenomena reveal definitely enough a combination of the two diseases. The danger is lest the development of the tuberculous lesion under such circumstances is not recognised; and my observations have led me to the conclusion that not a few cases regarded as bronchitic are in reality phthical, and that they are so recorded in death certificates—a most important matter in relation to life assurance and to the question of the heredity of phthisis. This oversight is especially liable to happen in the case of patients advanced in years, a statement in support of which I could mention many examples from personal knowledge.

(f) Pleuritic and Pulmonary.—These combinations frequently present themselves under different aspects in practice, but I can only give a few of the more prominent illustrations. Firstly, we have the fairly simple cases, in which, as the result of a definite attack of pleurisy with effusion, or perhaps an empyema, the effects produced by these conditions on the lungs remain persistent, though there is no further active mischief in these organs. That is to say, the lung on the affected side continues in a more or less condensed or collapsed state, being bound down by pleural adhesions, probably becoming also in course of time somewhat fibroid; while the opposite one presents various degrees of distension or compensatory hypertrophy. This combination may remain quiescent for an indefinite period. Secondly, it must be borne in mind that pleural adhesions are most important factors in a large number of cases belonging to the pulmonary groups considered under the previous heading. In chronic phthisis, for instance, it is quite common to find one lung universally adherent, the change often extending much beyond the limits of the actual pulmonary disease, while the opposite organ may be also partially fixed in a similar way. Of course, in some of these cases the phthisis is secondary to the pleuritic condition, but the lesions as they come before us are practically the same. It is at the present time a favourite doctrine that most cases of pleurisy are originally tuberculous; although I do not agree with this doctrine as a general statement, I fully recognise the great importance of pleuritic conditions in relation to phthisis. Local adhesions

are very frequent in association with emphysema and bronchitis. A somewhat complicated class of cases occasionally present themselves which, without due care, are very liable to be regarded as merely "emphysematous and bronchitic." Their history is that the patient has had a distinct attack of pleurisy which has left one lung universally adherent and probably somewhat compressed, while the opposite lung has undergone compensatory hypertrophy. In course of time, however, the enlarged organ becomes truly emphysematous, and ultimately greatly distended, while the compressed lung may also expand under certain circumstances, and subsequently become emphysematous. Thirdly, there are definite cases of a chronic phthical nature in which pulmonary and pleuritic lesions exist together in a pronounced form, including, perhaps, the remains of a pneumothorax, and the combination may be very perplexing. Occasionally one meets with phthisis at one apex and an effusion on the opposite side, which returns again and again after removal by paracentesis, being evidently of a tuberculous nature. Lastly, an important class of cases, where the pleura and lung are involved together, are those in which an empyema has burst into the lung, and the discharge of pus in this direction has persisted as a chronic state, the matter being usually coughed up at intervals. In short, we have then to deal with a pyo-pneumothorax which is periodically emptied, partially or entirely, by way of the air passages.

B.—Pericardial, Cardiac, and Vascular.

A systematic and comprehensive knowledge of the various chronic morbid conditions which may affect the pericardium, heart, and great vessels is particularly helpful to a clinical observer. Of course, it is quite out of the question to give in these lectures any classification of the several ways in which these morbid conditions may be associated, and without further comment I can only submit the following propositions:—

(a) That a large proportion of cases of cardiac disease are, in relation to the structures immediately concerned, by no means so simple as they are often thought to be, and that most of them must inevitably at some period or other of their history present various combinations of morbid changes.

(b) That pericardial adhesion or agglutination is a most important element in not a few chronic heart cases, and should therefore always be borne in remembrance, especially as it can frequently be easily recognised.

(c) That in every individual case it is essential to think of all the conditions associated with the heart itself, and to study them intelligently, being guided by an adequate general knowledge of the probable combinations which may be anticipated under particular circumstances. I may allude here to the fact that it is quite common to find two or more orifices and their valves affected in the same case, and the well-known consequences of these lesions will be modified accordingly.

(d) That functional disorder of the action of the heart does often modify from time to time, or even persistently, in a remarkable way and degree, the phenomena associated with organic cardiac affections, both symptoms and physical signs, and it should therefore be made a rule to study systematically in every case the mode in which the heart is performing its functions, in relation to the organic changes that happen to be present. In short, we have frequently to deal with a combination of organic diseases and functional derangement of this organ, which it is most important to recognise.

(e) That it is also of the highest importance always to attend to the great vessels within the chest and those of the neck, as these are commonly affected in various ways along with the heart, or may reveal conditions of this organ which cannot otherwise be definitely determined. The frequency of extensive atheroma or calcification of the aorta and its large branches in cases of cardiac disease ought never to be forgotten, or there may even be dilatation or an aneurysm.

C.—Respiratory and Circulatory.

The next group of chronic chest cases of a combined nature is that in which the respiratory and circulatory apparatus are involved more or less at the same time. We often meet with combinations exemplifying, on the one hand, the effects of mitral disease on the lungs, and, on the other, those of prolonged emphysema and bronchitis upon the right heart. Again, when the lungs are highly emphysematous the heart and pericardium become more or less completely covered, while at the same time the right side of the heart seems to be pushed down towards the epigastrium. On the other hand, as the result of contractile changes in connexion

with chronic phthisis or pleurisy, the pericardium and its enclosed structures become unduly exposed, or the large vessels may be also uncovered. A very large heart compresses the left lung more or less, and I have known the organ to be completely collapsed and airless from this cause. Another class of cases in which the respiratory and circulatory apparatus present combinations of chronic morbid conditions are those where the changes are the effects of the same cause or causes, which have operated upon both sets of structures. As I shall show in the next lecture, they may be involved in a acute inflammatory process at the same time, and the remains are likely to come before us under a more or less complex aspect.

D.—Special Diseases.

Under this heading I allude to certain classes of chest cases, each of which demands independent study and consideration, including especially aneurysm, glandular enlargements and other solid tumours, hydatids, actinomycosis, and œsophageal pouching. These severally give rise to various combined morbid conditions, but I can only offer two or three general remarks about aneurysm and glandular enlargements, or other kinds of intra thoracic tumour. It is necessary to be constantly on the look-out for these kinds of cases, and especially aneurysm, for, although they are of comparatively infrequent occurrence, we never know when they may come under our notice. Enlarged bronchial or other glands within the chest is another condition to be remembered, especially in children. In relation to a thoracic aneurysm or solid tumour, we have not only to think of these conditions in themselves, but also of their effects upon adjoining structures. An aneurysm of the aorta may come before us under the guise of what appears to be a mere case of "emphysema and bronchitis," the result of pressure on the trachea the aneurysm itself being entirely obscured by the distended lungs, and out of reach.

E.—Independent Diseases.

Under this head I only wish to say that there are cases of chronic chest disease in which morbid conditions are associated together, having no direct connexion with each other, and being in reality quite independent. For instance, I have met with not a few cases of phthisis and cardiac disease which would come under this category, as well as exceptional instances of aneurysm and phthisis. Another illustration is the association of right pleurisy with cardiac disease, and if time permitted I could give from my own experience numerous other examples.

F.—Highly Complicated Conditions.

I have already given examples of combined chest conditions of a complicated nature, and I merely remark further that exceptionally they present such a degree of complexity, that it becomes practically impossible to unravel them, apparently every structure connected with the thorax, both internally and externally, being more or less implicated in the morbid changes, and ultimately becoming either agglutinated and matted together into one mass or involved in a common ruin. Some highly complicated cases, however, can be fairly understood, even when several structures are affected.

Permit me, before bringing this lecture to a close, to submit the following general conclusions: (1) That chronic diseases of the chest, even of individual structures or organs, to which we apply particular names, are in reality usually made up of different morbid conditions in various combinations; (2) that two or more directly related structures are frequently implicated, and present well-recognised associated lesions in cases which are thus designated; (3) that definite and well-understood pathological relations exist between the important organs occupying the thoracic cavity, which explain many of the combinations of morbid conditions met with in medical practice, but also that these, and the structures associated with them, may be implicated together, apart from the effects of any such obvious relations; (4) that certain classes of cases must be dealt with specially and individually, as regards the morbid combinations which they are likely to produce; (5) that we must be prepared for cases in which separate and independent diseases exist together, as well as for those in which the changes are of a highly complicated nature, and which may tax our knowledge and skill to the utmost in our attempts to unravel them; and (6) that in all cases of chronic thoracic disease due attention and consideration must be given to the chest walls, and that in not a few instances, at any rate, the diaphragm ought not to be forgotten or overlooked.

An Address

ON

EXPERIMENTAL CRANIOTOMY AND DIAGNOSIS OF CEREBRAL ABSCESS.

By PROFESSOR AUGUSTO MURRI, M.D.,
PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF BOLOGNA.

Delivered on Nov. 36th, 1894, before the Lombard Medical Association, and specially reported and translated for THE LANCET.

(Continued from page 84.)

LAST April a man aged thirty-three years, who for five months had been suffering horribly from headache, was admitted to the medical clinic. The pain was so great as to prevent sleep, forcing him to rise at night and even to throw himself upon the ground with agony. These phenomena had increased, but for nearly five months had not led to the slightest anomaly in the function of the brain. Only twelve days before admission the patient had one evening been seized with an attack of vomiting, which was repeated four consecutive days, always after a meal. Notwithstanding all this, he was still able to rise from his bed; but for about a week this, too, had become impossible. At the same time his family noticed that when left alone he fell into a slight delirium, and that for four days his face flushed suddenly every now and again. In spite of this, the physician who attended him at the time found no fever. Consciousness grew less and less acute, till at last the patient could no longer speak, in spite of his efforts to do so. His right eye remained half closed; at times attacks of coughing and hiccuping seized him; and finally, on sinking into coma, the patient was removed to the clinic, where he survived only one day. In this case slight ptosis on the right side was noticed, deviation of the eyeballs towards the right, and occasionally horizontal nystagmus. There were no contractions of the muscles of the neck, but those of the trunk, and especially of the chest, were contracted, and the muscles of the upper limbs were in a state of increased tonic spasm. The mental condition, which was very serious, did not allow any really voluntary movements or permit any control over the different senses; only in the upper limbs a few spontaneous movements were to be seen; there were fibrillary twitchings and occasional clonic spasms everywhere. The plantar reflexes were very difficult to get, those of the cremasters and of the abdomen were altogether absent; the tendon reflexes were everywhere slightly exaggerated; there was increased mechanical excitability of the muscles; the reflex action of the conjunctive and pupils was wanting. There was pronounced exophthalmos in both eyes, especially in the right. An ophthalmoscopic examination showed perfectly normal conditions. The breathing was a little irregular; rhythmic pulse; the temperature was 37.6 C.; the respiration was 20, and the pulse 120 to the minute; the urine was normal; slight râles were audible in the lower and hinder parts of the thorax; there was nothing abnormal in the other viscera. What was the cause of these serious symptoms? The patient showed signs of tuberculous disease of bone, a cicatrix adhering to the bone of the right leg, the remains of a sinus which had lasted several years; another sinus was still open in the right forearm, which, having opened spontaneously, maintained a continual flow of pus; all round was diffused swelling, due to periostitis. Certainly, therefore, the idea of tuberculous meningitis appeared in sufficient accord with the preceding and coexisting facts; but other facts did not so easily agree with it. There are morbid processes which will ever be the despair of writers on disease; one of these is tuberculous meningitis. Imagine a complicated organ like the brain, a variable disease like that produced by Koch's bacillus, and tell me if it is possible to lay down any rules sufficiently probable for the infinite ways in which these two agents acting together may give shape to their results. Naturally they will be varied by the duration, situation, and extent of the tuberculous deposit, by meningitis and reactive encephalitis, by the previous constitution of the patient, by the excitability of his nervous system, and by the absence or coexistence of similar or different conditions in other organs. But one of the most assured facts is fever. The presence of tubercles in the choroid is very important, but although

diligently and repeatedly searched for in this patient they were not discovered. Another fact of less importance but not of slight value is the length of the illness. All who have observed this disease have seen it take its whole course in a few weeks; it is exceptional if the patient does not die in a month. Nor is this difficult to understand; it is enough to recall the devastating action of Koch's bacillus and the importance of the organ affected. Now in the case under discussion there was no fever—at least, the physician never discovered it,—although the beginning of the illness could be traced back five months. Kraemer¹ refers to a case which lasted four months, and speaks of those of Seitz of forty-two and fifty-four days' duration; Gatti of Milan observed one lasting seventy-nine days; Dickinson noted one of eight months' duration. I myself have seen a case lasting even longer than this, but in it between the beginning and end of the disease there intervened a long period of apparent recovery. The patient was a girl aged seventeen years, whom I, having made the diagnosis of tuberculous meningitis, did not permit to leave the clinic notwithstanding her evident return to health. She remained there for several months, willingly occupying herself in various little duties belonging to the nurses, but was once more seized with serious cerebral symptoms, and finally died. The post-mortem examination entirely confirmed the diagnosis of tuberculous meningitis. In the patient, however, whose history I gave above it was difficult to explain so long a duration, seeing that there had been no interval of apparent recovery; but that, on the contrary, the symptoms had been continuous and progressive. Persuaded of the infinite variety in the disease, I did not exclude the possibility of tuberculous meningitis in that case, but declared, nevertheless, that I inclined rather to the following diagnosis: caries of the base of the skull; pachymeningitis, with an extra-dural abscess compressing the posterior part of the right cerebral peduncle and the anterior part of the right side of the pons. The pain, which had been so great and continuous without any other phenomena, seemed to me to be best explained by this affection of bone and by pachymeningitis: the sudden nature of the final symptoms were signs of the spreading of the meningitis; the right ptosis, the very evident deviation of the eye, the nystagmus, &c. all justified the diagnosis of lesion of the peduncle and pons, occasioned by compression from below. The post-mortem examination showed that this diagnosis was right as regarded the seat of the disease but wrong as regarded its nature. The skull bones were perfectly normal and the dura mater scarcely thickened. There had been tuberculous meningitis, not an abscess. The convolutions were sunken and the fissures nearly obliterated. In the posterior cranial fossa was found a turbid yellowish liquid. The pia mater was everywhere injected, thickened, and opaque; there were evidences of grey and yellow tubercles in the left motor area and in the parietal lobe of the same side. The sides of the fissure of Sylvius were very adherent, and the middle cerebral arteries—especially the right one—were buried in false membrane and yellow tubercles. The great longitudinal fissure was also obliterated in its anterior part. On the base, from the posterior part of the chiasma to the front of the pons, was found abundant exudation, and the corresponding parts of the brain were covered by pseudo-membrane lying more to the right than the left. The third and fourth ventricles were dilated and full of a turbid liquid, but not the lateral ventricles. The brain tissue was softened in the posterior part of the corpus callosum and in the posterior and anterior parts of the left optic thalamus. The right cerebral peduncle was also softened, while the left had remained normal; the locus niger was more marked on the left. In the pons the base was inclined obliquely from the right to the left from above downwards; the upper right half of the pons had shrunk as though crushed, and presented on its lower side a dark clot as large as a small lentil. On cutting through the pons it was found that the tissue on the right was of a dark colour, while on the left it was of a pale red; the consistence was less on the right, although the softening appeared less general here than in the posterior part of the right peduncle.

In some cases it becomes impossible to distinguish between tuberculous meningitis and cerebral abscess, for if the observations of Fränkel and Rendu be accurate it would seem that Koch's bacillus is enough to generate a cerebral abscess. A man thirty-four years of age died in my clinic in whom three cerebral abscesses of quite recent date were

found, one in the genu of the corpus callosum, the other two in the white masses of the two hemispheres. Neither by post-mortem examination nor by the past history could any reason be found for them; but the cerebral meninges of the pia mater gave evidence of a quantity of recent tubercles. But beyond this it is well known that the usual tuberculous deposit in the brain is seldom found surrounded by suppurating brain substance. I therefore firmly believe that between caries of the cranial bones and cerebral abscess there exists a decided causal relation, and that there is the same relation between the suppuration of the tissues which surround the cranium and cerebral abscess. But I admit that between this theoretical decision and the clinical proof which may have verified it in an actual case there is a great gulf. In practice it is often difficult, not to say impossible, to decide whether there has been a cause or not; but even after having ascertained this it is not fair to argue the existence of the effect, seeing that the same causes may lead to so many different effects; caries of the bone may cause either an abscess, meningitis, thrombosis of a sinus or tuberculous, or, on the other hand, none of these; an injury may produce abscess, tumour, traumatic neurosis, or, again, none of these. Those who write on pathology, therefore, delude themselves; etiological criticism is, without doubt, very important in the diagnosis of an abscess, but one must confess that it is also very dangerous. What symptomatic difference of importance can be found between the case I have narrated and the one I am about to give? I leave you to judge.

On Aug. 16th, 1890, a man thirty-five years of age was admitted to the clinic. He was in a state of half-delirium, half-stupor, so that little could be taken for granted in the answers he made; but his wife when pressed assured us that the man had never suffered from ill health. It was only in the beginning of that month that he complained of headache, which soon became so intense that after Aug. 7th he could no longer leave his bed. When he tried to do so he found that he had not the strength. His mental condition, which from the beginning had been abnormally irritable, rapidly grew duller. The night before his admission into the clinic slight delirium and a very slight stupor had appeared for the first time. The man was well nourished, and showed, besides the delirium and somnolence, a few muscular spasms, and gave vent occasionally to cries of pain caused by the headache, but he had little fever. At the physical examination the next day his mental condition impeded any accurate study of the eyes. The pupils were equal, but reacted slowly. The tongue deviated towards the left. Sensation was dull everywhere. Spasms and contractions occurred in all the limbs. The pulse was 66 and the respiration 20 to the minute. The stupor did not, however, remain always the same; in the following days he sometimes answered promptly. The spasms continued even during sleep. On Aug. 22nd dilatation of the left pupil was noticed; on the 23rd there were contractions of the muscles at the back of the neck, ptosis of the right side, and deviation of the eyes and head to the right. Reflex action was normal everywhere, general sensation was obtuse and the sense of smell quite gone. On the 25th convergent strabismus on the left from paresis of the external rectus set in; the left eyeball was painful, and there were dilatation of both pupils, paresis of the facial muscles on the left, and inability to protrude the tongue. On the 27th paresis of the left side set in; the perception of pain was very slow, but the muscular sense of the position of the limbs was fairly good. The pulse remained regular. Nystagmus of the left eye and a tonic spasm of the right arm, with flexion of the forearm upon the arm and of the hand upon the forearm, were present. Reflex action of the cornea and conjunctiva of the left eye was slow and weak, while the right continued normal; the movements of the left eye were very weak, those of the right eye were very quick. The abdomen was sunken, with an occasional loose motion; deglutition grew gradually more difficult owing to defect of the reflex action in the pharynx. The headache continued intense, while, on the other hand, the stupor grew daily deeper, until by Sept. 12th it had reached the degree of absolute coma. The pulse rose to 120-130 beats to the minute, the breathing to 24-28; the temperature reached and went above 39° C. several times. He was almost always feverish, with the exception of two periods (from Aug. 25th to 29th and from Sept. 3rd to 11th) in which he remained at 37°. The facts given with regard to the nervous system persisted steadily, until on Sept. 14th the man died.

Whoever in this case had chosen to make a diagnosis of basal meningitis would certainly have had no less reason than

¹ Ueber Meningitis Tuberculosa. Inaugurale Dissertation. Zürich, 1894.

one who made the same diagnosis in the preceding case; indeed, in the last the case had been shorter and the difficulty of the long duration was less; besides, there was fever, alternated with periods of apyrexia, which are frequent in cases of tuberculous meningitis. It is true there existed no disease of the bone, as had existed in the preceding case, but who can deem himself free from any old caseous process of the mesenteric or intra-thoracic glands? As in the preceding case, there was no tuberculosis of any organ here; in this case, as in the other, a number of nervous symptoms existed which coincided very decidedly with an extensive process at the base of the cranium—paresis in the left limbs, spasms, starting and contractions in the right limbs, ptosis in the right eye, paresis of the left external rectus, anaesthesia of the olfactory nerves, diminished sensation of the trigeminal and pain in its branches, nystagmus, permanent deviation of the eyes and head, paresis of the hypoglossal, beginning on the left, and symptoms of cerebral compression increasing hourly. Nevertheless, all the meninges were everywhere normal. The origin of the symptoms was one, no, three, cerebral abscesses, one as small as a pin's head on the anterior right side of the pons, in the vicinity of the nucleus of the sixth nerve; another, also small and easily enucleable, as large as a nut, in the anterior part of the left temporal lobe. The largest of them occupied part of the optic thalamus, the internal capsule, and the lenticular nucleus of the right hemisphere, but without breaking through the ventricular surface. This abscess was coated with a pseudo-membrane of considerable resistance, was of a winding form, as large as a fowl's egg, and contained an incoherent, greenish pus of the consistence of syrup. It had caused great compression beneath; indeed, an examination of the corpus callosum showed at the junction of the anterior and the median third a roundish prominence, which penetrated the right hemisphere and fluctuated. Studying the lower surface of the brain, the hippocampal gyrus was noticeably displaced by a marked prominence, something like a bud, of the interpeduncular space and the right cerebral peduncle. The right optic tract was compressed and presented the appearance of a ribbon, as also were the third, fourth, and sixth nerves of the right side; the chiasma and the left cerebral peduncle were compressed and displaced to the left; the right anterior half of the pons was also compressed, and the third ventricle and the right lateral ventricle crushed and almost obliterated. What had been the cause of these abscesses? Just as the past history had yielded no explanation, neither did the necropsy. An examination of the viscera showed nothing abnormal in them. The bones of the cranium seemed to be sound, and the questions which had been asked during the life of the patient had allowed of no suspicion of trauma in the head. The temporal bones, with their contained auditory apparatus, were removed, but the most diligent search showed no alteration in them. Were these, perhaps, idiopathic abscesses? The question may be attractive in theory, although, even thus considered, it appears difficult. Who in these days can declare that the brain suppurates without any sepsis having set in? And who will deny that Martius was right in holding that these provocations to suppuration arise in the depths of the encephalic mass, running through the most delicate paths of the circulation? But for the purposes of diagnosis this solution is not sufficient; it is a certain fact that abscesses of the brain are often found of which the sources and causes cannot be discovered during life, or even after death; so that the principal foundation of diagnosis is entirely lacking in these cases, which nevertheless, according to Gowers' statistics, represent the sixth part of the whole. If in such cases, as often occurs, even fever is absent, what is practically left to prove the nature of the disease? Sometimes the course of the illness, but even this criterion, although the best, is often dangerous. Twice I myself have erred in following it: once I made the diagnosis of tumour and found an abscess; another time I imagined an abscess and there was none. I know that the description of so many cases is annoying, but facts are always more satisfactory than precepts, so you must permit me to recount them as briefly as I can.

One day I was called to a consultation near Bologna, and found a patient already under the care of two young and extremely clever colleagues of mine. At first they had suspected the illness to be sciatica, but had not been able to decide whether it was peripheral or central. The patient was a strong man twenty-nine years of age, in the habit of

travelling from fair to fair on matters of business. It was during a fair, to which he had gone on foot, that he declared he had been taken ill; that suddenly the left leg had grown so weak that he was obliged to cling to something firm for support, after which the lower limb had become painful both in itself and to the touch. But the patient, intent upon his sale, did not take much notice of his health. When I visited him I soon observed that the muscles of the lower part of the left side of the face were slightly weak, and neither I nor my colleagues felt much doubt that the pain and weakness of the left limb did not arise from the peripheral nerves or from the spinal cord, but from the brain. Until now, however, this last appeared in a perfectly normal state. I hazarded the possibility of cerebral tumour, and it was decided that the man should be removed to the Bologna clinic. I have recalled these particulars in order to demonstrate how misleading the beginning of cerebral disease may be. On Dec. 15th, 1892 he was admitted to the clinic. There his past life was thoroughly inquired into, but nothing could be learned beyond that he had once suffered from gonorrhoea, from an intermittent fever, which had long left him, and from an attack of influenza which had some years previously troubled him, but which had been cured some time ago. Of actual disease nothing, absolutely nothing, could be noticed. But patient and oft-repeated interrogations at last elicited the fact that during the last three days in November he had experienced a pain in the right side of his head and a certain sense of fatigue. These symptoms continued until, on the morning of Dec. 6th, he noticed that his legs were weak. Nevertheless, he left the house and went to the market on foot, and it was there that suddenly an indefinable discomfort came over him and he felt his legs giving way beneath him. Being, however, in full possession of his senses, he sought support against the shoulder of an ox and made signs to the first cabman who passed to take him home. He said that when he had reached home and sat down he felt his left leg become straight and rigid, and he noticed certain movements in the toes of the foot. Having called in a physician, he was ordered a plaster upon the thigh, probably on account of the pain of which he complained. All the movements of the left lower limb seemed weakened. This painful paresis of the left lower limb grew so much worse that the patient could scarcely leave his bed, and some days after the left upper limb began to show signs of weakness. The slight headache continued and became for the most part frontal. Consciousness was still intact, although the man appeared to be a little apathetic. An examination showed a flaccid hemiplegia on the left. The loss of voluntary motion was complete. The patient rested constantly upon the right leg, and the eyes and head evinced a slight deviation to the right, which lasted to the end. The arch of the left eyebrow was higher than the right, and the skin of the right eyelid was more drawn than that of the left. There was weakening of sensation and of sensibility to pain on the whole of the left side, while the muscular power was also weakened. On the left there was loss of cremasteric and abdominal reflexes, the plantar reflex was weaker than on the right, and the knee-jerk and tendo Achillis reflex were stronger. The pupils were of ordinary size, but reaction was slow; the sight was almost normal, but the motion of the eyeballs less free, especially on the left. The optic papillae were red, turbid, slightly raised, with indistinct outlines. In the retina around the disc was a greyish turbidity, which extended also to the papillae and obstructed the view of the course of their vessels. The veins were swollen and tortuous and the arteries thin. These alterations were more marked on the left than on the right. Acuteness of sight was well preserved, but the sense of taste was confused all over the tongue. Hearing and smell appeared normal; normal also were the urine, pulse, respiration, and temperature. An examination of all the viscera was negative. The condition of the patient grew rapidly worse, and a certain degree of stupor and apathy, which had existed from the very first, became so much more marked that several times he passed his motions in bed either from not being in time to call or from a desire not to be disturbed. He ate little and never had any attacks of vomiting. His only complaint was the headache. On the morning of Dec. 21st he sank into coma and towards the evening died. The temperature, which had been normal until that morning, rose rapidly to 39.9° C. (103.8° F.) at the moment of death, and the pulse and respiration became at the same time very frequent. Beyond this no new symptom preceded death.

I had confirmed my former suspicion of cerebral tumour since he had been in the clinic, and had localised it in the right centrum ovale, with successive invasion of the optic thalamus and corpus striatum and compression of the internal capsule. The absence of any signs of irritation had excluded the idea of its location being in the cortex, and the absence of all paralysis during a certain period of the illness did not lead me to suspect the internal capsule as the original seat of the morbid process. The rapid and complete implication of the fibres in the internal capsule obliged me to believe that this morbid process, not having originated with them, could not be far off, since it had so quickly reached and invaded them. The sciatic pain in the beginning and the succeeding persistent diminution of sensation made me fix upon the optic thalamus and its surroundings as the seat of it. And in point of fact these diagnostic indications led me comparatively right with regard to the seat of the disease, but the diagnosis of its nature was wrong. In the right hemisphere of the brain a considerable softening, corresponding with the upper parietal convolution, was noticed. On separating the hemispheres the inner surface of the convolution of the corpus callosum of the right side was remarked to protrude like a sac, which was yellowish green in colour and contained a large quantity of very fetid, yellowish-green pus. Making an incision into this convolution an abscess cavity was found of the length of from 5 to 6 centimetres and width of from 2 to 3 centimetres, which included the grey substance of the convolution. This cavity was lined with a dark, hard, easily enucleated membrane, and the layer around it was softened and showed upon its surface innumerable minute red spots. This cavity communicated with another abscess, of the same size and aspect, situated nearer to the centrum ovale, but not involving the grey substance. This one ran underneath and behind the fibres coming from the upper parietal convolution, and passed beneath those coming from the paracentral lobule, terminating at the foot of the first frontal convolution. The right corpus striatum was softened and a little compressed from above downwards, as was also the corresponding optic thalamus, the upper side of which was concave, while the inner was perpendicular, so that the two sides formed a right angle. Looked at from above it had a triangular form, and its substance was very vascular. The grey layer of the right hemisphere was so faded as scarcely to be distinguishable from the white. The left hemisphere appeared to be normal, as were also the vessels, the meninges, and the bones of the cranium, including the petro-mastoid of the right temporal, which was particularly examined. Every sign or symptom had been lacking during life which might have led to the discovery of this great cerebral abscess; there had never been fever, and none of the well-known causes of suppuration of the brain had preceded it. Even after the necropsy had been made the doubt as to the origin still remained; it was certainly not a traumatic abscess, nor a carious one, nor one arising from suppurative otitis. Could the influenza be blamed? The position of the abscess and the fact of its being double were characters favourable to the hypothesis of a pulmonary origin, but even so, what explanation could be given in the clinic of these diseases which are to be met with every day and every moment and which are not followed by abscess? The explanation at the best might serve the purpose of the pathologist after the examination of the body, but for the physician who must diagnose before the necropsy the idea is utterly worthless. Certain it is that death intervened sooner than is usual in the case of tumours, but there are tumours, especially infiltrating sarcomata, which rapidly cause such intense compression that death comes through excess of intra-cranial tension. In fact, the cause of the patient's death was none other than a rapid increase of this tension. The abscesses had been there for some time, as was shown by their thick, hard capsules. In less than twenty-five days, during which the patient had complained of pain, the pseudo-membrane might have been formed, but the capsule could scarcely have attained such thickness or such resistance. Before that time the patient had never noticed that anything was wrong with his head. Perhaps a slow extension had at last caused the communication of the two abscesses, after which the growing activity of the membrane had brought about an increase of the liquid contained in the two cavities, until the right hemisphere, and especially the optic thalamus, had been violently compressed. A sarcoma or glioma of rapid growth might easily have caused the same physical effect. Therefore I ask, What signs could the physician bring to the

solution? The causes? they were not known. Fever? there had never been any. Optic neuritis? it had been verified, but if its presence were not unfavourable to the abscess it is certain that it was not favourable, since it seemed to have arisen very quickly. And still this helplessness of diagnosis before the post-mortem examination, which showed that a surgeon's work might have saved a young and vigorous life, does not suffice to bring to a physician the calmness of resignation. But so long as surgeons, ignorant of the real conditions of diagnosis, deluded by the few and hazardous diagnostic successes related in contemporary literature, presume to act alone, or insist that an accurate diagnosis be given them before they will offer their help to sufferers from cerebral abscess, many lives must be sacrificed before their time, seeing that physicians and surgeons not deluded by scientific appearances, but severely instructed by facts in the clinic, can rarely feel sure of a diagnosis of chronic abscess of the brain, and may not propose or accept the intervention of the surgeon until all adverse signs and symptoms have been overcome. Decidedly the position of exploratory craniotomy is far more unfortunate than that of exploratory laparotomy once was. The cases are much rarer, the teaching of experience therefore much slower, the victories less apparent, and the mistakes serious and endless. I am the first to recognise that he who makes a diagnosis and he who operates lose much in the esteem of the public when the faulty judgment has led to a useless operation; but no man of worth, upheld by the feeling of duty, will be alarmed at consequences which the want of practical knowledge fully excuses.

In the meantime, in order to learn more we must lay to mind our mistakes. To gain knowledge by so thorny a path (who will not admit it?) is unpleasant, but how shall we evade it? Every mistaken diagnosis is a beneficent correction. It would be well if each of us would in charity give the results of his individual experience. This clinical art of ours, which looks so easy to him who surveys it from within the walls of a laboratory, becomes instead very difficult when one enters the hospital. I have spoken above of the deficiency of etiological criterion for the diagnosis of cerebral abscess. I have also remarked that often fever means little to the physician, but without these two things a reasonable foundation for suspecting abscess becomes impossible. Such was the case in the present instance, the cause (probably of long standing) of the formation of the two abscesses had been unsuspected by the patient and undeveloped by the past history—only the last phenomena of the deepening and increase of tension of the two abscesses had produced any impression on the consciousness of the patient. In similar cases, when of all the drama enacted nothing but the last scene is represented, how will it be possible to realise all the long and serious processes taking place before it? Will it be possible to infer from the final solution, not only the existence, but the kind of changes that in latent form were preparing this last and only change which was observable? It is certain that the rapid course of the symptoms observed in this case might as well have been attributed to sarcoma or infiltrating glio-sarcoma, but at the same time it did not exclude the possibility of an entirely latent abscess, seeing that science is able to show a few such cases. Hirt ascribes to the abscess the property of causing hemiplegia little by little and not all at once, and so it happened here. But a large tumour of the temporal lobe of the centrum ovale may compromise and paralyse the crural, brachial, or facial tract successively and produce the same hemiparesis or hemiplegia. Granted that on account of these symptoms one has harboured the idea of an abscess, only exploratory craniotomy could possibly verify it. The probability of diagnostic error is not limited only to the confusing of these cases with a tumour of rapid growth; it can extend even to meningitis and cerebral hæmorrhage. What is more, this confusion does not only occur when the last stage is not preceded by some absolute sign, but is incurred even when the end has been preceded by some suspicious symptom. These causes have often lasted a long while, till suddenly some softening, some inflammation in the surrounding parts, or more probably the breaking of the abscess into the ventricles or on the surface of the brain, causes a tempestuous onset of symptoms, followed by death.

On Dec. 3rd, 1892, a girl seventeen years of age was admitted to the clinic. She was a peasant who for four years had been in the service of a family in Bologna. She was born of healthy parents and had a tolerably strong constitution. She spoke little and with reluctance, but her relatives and employers furnished us with the following facts:

As a child she had suffered from measles, and once, when about three years of age, she had a fall which had caused a scalp wound, the precise nature and position of which were not remembered; but neither the measles nor this wound had left any lasting effects. The girl had enjoyed good health until about a year back, when she had an attack of diphtheria which left her weak and pale. A visit to the country and sea baths had taken away all signs of this affection. Nevertheless, she continued to be pale, suffered a little from the stomach, and was subject to a headache which for some years had been slight and infrequent, but which after the diphtheria had grown so intense as to burden the life of the poor girl. She had only had fever once, the cause and length of which could no longer be remembered, but which the patient declared to have been very high; but everyone agreed in affirming that for a month the troubles of head and stomach had increased and that the girl was weaker. Fifteen days before entering the clinic she had consulted a medical man, who noted gastric disorders with frequent eructations, sweats, coated tongue, and bad headache. He prescribed Carlsbad water, and four days later saw the patient and confirmed his first opinion of gastric catarrh, but the treatment did no good. Six days before her entrance into the clinic she, while mounting the stairs, had been taken with a giddiness which made her feel as though she would drop the baby she was carrying. The next evening, while carrying some bread to be baked, she suddenly felt so ill that she was obliged to return home and go to bed. The headache persisted, two days later vomiting began, and the evening before entering the clinic those in attendance on the girl noticed that her skin was dry and burning. The next morning fever had ceased; the medical man came and was much struck by her deathly paleness. He advised her removal to the hospital. The most salient points noticed by us were: extreme pallor of the skin and mucous membranes, much subcutaneous adipose tissue, and extraordinary frequency of breathing, equal to the pulse, 100 or 110 to the minute. This, however, ceased and went down to 18-20 to the minute during sleep or when the patient was left long alone and tranquil. Nothing abnormal was noticed in the thoracic and abdominal organs. The patient was taciturn, seemed determined to be silent, and lay almost always with her eyes shut or with the bedclothes drawn up so as to keep out the light and screen herself from inquisitive eyes. She complained of violent pain all over her. All movements were possible to her, but were slow and wanting in energy. The superficial reflexes were weak. Those of the tendons of the knee and arm were, however, normal. The pupils were equal and reacted to light, but were slightly contracted. The vasomotor reflexes were normal. An examination of the different senses revealed nothing, as the patient refused to coöperate, but what could be seen of them was normal, as also was the sense of touch and heat. The patient appeared to understand even whispered words; her sight was good and in the retina nothing was noticeable but great pallor; the outlines of the papillæ were distinct. From the way in which the patient behaved towards her relatives it was evident that she was fully conscious, while her words showed that she understood well and could answer clearly. The examination of the blood showed red corpuscles 2,808,000, and white corpuscles 446 in the cubic millimetre. An analysis of the urine presented no anomaly. For two days the girl lay quiet, slept well, and ate without vomiting or delirium; but on Dec. 5th she was seized with clonic movements of the arms and part of the face; the lower limbs were not convulsed and consciousness was lost. The convulsive movements lasted only a few minutes, but she did not recover consciousness for nearly an hour. The following days were without incident. She was taciturn, drowsy, tormented with bad headache, and had a temperature always between 37.8° C. (100° F.) and 38.2° C. (100.8° F.); pulse and breathing very abnormal, as had been observed at first. She was tolerably conscious. On the evening of Dec. 9th the patient, as usual, had had her supper, had sat up in the bed, and had exchanged a few perfectly connected words with the nurse. But less than an hour later she was seized with an attack of convulsions, which began with a cry, then clonic distortions of the right side of the face, whence the convulsion extended to the right upper limb, to the left side of the face, and lastly to the left upper limb and to the lower limbs. The eyes deviated to the right. The convulsion, once become general, assumed the form of tonic and clonic contractions. The head was turned alternately to the right and left. The mouth was full

of froth, the lips became blue, and the skin was covered with perspiration. After a few minutes the convulsion ceased, but very soon began again. Between two attacks there was an interval of ten minutes, and this state of things lasted from eight in the evening till midnight. During the intervals tracheal râles began to be heard. Consciousness, which had still been present during the first attacks, grew slowly dimmer, until at last it was entirely lost. At midnight the attacks grew yet more frequent, but later diminished again, with intervals of fifteen minutes, until 3.45 A.M. on Dec. 10th, at which hour the patient died. In this last phase of convulsions the pulse never rose higher than 116 during the minute and the breathing stopped now and then during the convulsion, while in the intervals it was 28 to the minute. An ophthalmoscopic examination being made during one of these intervals showed no change, with the exception of a little inflammation of the centre of the papillæ. Five hours before death the temperature marked 37.6° C. (99.8° F.). This strange series of facts was decidedly not easy of explanation. Nevertheless, the violent headache which had lasted a year, the giddiness and sudden falling experienced a week before, and the stormy scene which had so tragically closed her life did not allow of any suspicion of a common vascular lesion (hæmorrhage, embolus, thrombosis). Even for meningitis there was no valid argument; nothing in the pulse, no delirium, no contraction of muscles, not even a sign of peripheral invasion of the cranial nerves; on the one hand, some insignificant premonitory symptoms of remote date, on the other, an incomprehensibly rapid and stormy end. It seemed more probable to imagine a tumour almost latent for an indefinite period, which had suddenly been followed by a period of rapid vascular overgrowth, and finally internal hæmorrhage within the new growth. Yet the slight fever which had been noticed, the absence of every intimation of the locality, and above all the absolute integrity and indeed pallor of the papillæ rendered such an hypothesis improbable. The idea most in accordance with facts was that of a chronic abscess. The reason for this probably lies in the fact that there is no limit to the course taken by an abscess—from one or two days to twenty years, from absolute latency to the most serious and decided manifestation. The violent headache dated from the diphtheria; had the wound of the head made during childhood perhaps left one of those encapsuled abscesses which seem to be healed? And even if this hypothesis is not accepted, why should we not have recourse to another process, certainly rare, but nevertheless ascertained as possible—a process of infection by the nasal mucous membrane? The headache, the anæmia, might be due to some febrile abscess of unknown origin which had for a year produced the symptoms of a semi-latent abscess; after which a period of renewed activity had come, and the giddiness, vomiting, increased anæmia, loss of strength, increase of headache, slight fever, the first access of convulsions, stupor, and diminution of mental powers were all explained by inflammatory œdema, and the softening of the cerebral tissue around the abscess. Then at last the work of expansion, conquering the weakened resistance of the surrounding tissues, overcame the last barrier and the pus flooded the ventricles; from this had arisen the uninterrupted epileptoid fits, followed by coma and death. Keeping in mind the constant lack of phenomena from a central infection and the frequency with which the latent or semi-latent chronic abscess is found in the temporal lobe, and remembering also the fact of the convulsions being on the right, I made this diagnosis: "chronic abscess of the left temporal lobe." On opening the cranium nothing was noticed in the bones, nothing in the dura mater; the pia mater was moist and transparent, and the veins injected. The superior longitudinal sinus contained two soft clots. The hemispheres were normal in size, in depths of sulci, and in convolutions; but in the left hemisphere, behind the first and second temporal convolutions—that is to say, in the convolutions leading to the second and third occipital convolutions—there was discovered a prominence of reddish hue, soft, and covered with dark spots. Cutting open the brain this zone appeared larger than a nut; it had a yellowish-green colour, and was marked with innumerable dark-red spots of various sizes, surrounded by a paler greyish-red substance. The delimitation of this zone from the rest of the cerebral matter was not well marked, but died off by degrees with the progressive diminution of the spots; the œdema, hyperæmia, and the swelling of the cerebral matter extended very noticeably to the surrounding tissues, but

there was no hydrocephalus. On the surface of the temporal lobe was a large vein quite thrombosed, into which there entered two other veins, also with clots, one in the front, coming from the limiting convolutions of the Sylvian fissure, and the other coming from the occipital lobe. All the smaller branches in these veins also showed signs of thrombus. The thrombi were red, without any sign of organisation. The examination of the walls of the veins and of the sinus showed nothing unusual. Of the numberless hemorrhages the most noticeable scarcely reached the size of a millet seed. They were very close to one another, oval or round in shape, of recent growth, and spread over all the grey layer. The lymphatic perivascular spaces were as a rule larger than usual, and no sign of leucocytes could be found in them. The nerve cells, with nuclei of good colour, seemed atrophied. This atrophy was very noticeable, especially in places, yet nowhere were the cells quite obliterated. The neuroglia presented a granular aspect, and here and there a certain cracking was noticed in the cells, a tendency to form vacuoles. There was no sign of small-celled infiltration either in the grey or the white matter. The rest of the brain was normal. It was not possible to open the cavity of the thorax and abdomen, but examination made during life had shown tolerably well that there could be no important lesion. Pathologically, therefore, the case stood thus—grave chlorosis with chlorotic thrombus of the left lateral sinus and of the cerebral veins. It was utterly impossible to decide which had been the first to coagulate, the blood of the sinus or of the veins, since the thrombus everywhere appeared to be of recent date and with no appreciable differences.

That the blood of chlorotic persons has a tendency to coagulate is well known from many observations; but, as a rule, the thrombosis shows itself in the lower limbs. Skeritt, in a discussion held in 1885 at the Clinical Society of London, affirmed that he had also seen chlorotic thrombus in the cerebral arteries. The first detailed statement made with regard to the chlorotic thrombus in a sinus² was Professor Bollinger's. His publication was more anatomical than clinical, since the girl he studied had apparently not attracted much attention during life. I learned later, from a kind personal communication from my cultured colleague at Monaco, that after this case he had been able to observe others which he will later publish. Bollinger's hypothesis, which attributes the coagulation of the blood to the fatty degeneration of the endothelium of the sinus, we could not ourselves confirm, notwithstanding the fact that we directed our attention to it. Not long ago Kochel was able to gather about half a dozen cases of chlorotic thrombosis of the cerebral sinuses.³ Looking over the history of my patient, one can affirm that the change from a country life to that of a city life was for her, as it is for many like her, who have to go into service, the first cause of a slight chlorosis, which after the diphtheria grew worse. Notwithstanding the transitory benefit gained by the life in the country and at the seaside during the summer season the illness grew worse again, and owing to the fatigue and deficiency of sleep which these poor girls often have to undergo the chlorosis became serious, was followed by giddiness, faintness, loss of strength, increased headache, and finally by clotting, and with it cedema, turgescence, and the softening of the cerebral substance; after which ensued stupor, slight fever, difficult breathing, slow cerebration, convulsions, coma, and death. Yet before the necropsy how probable had seemed that suspicion of semi-latent abscess which broke at last into the left lateral ventricle; and after the necropsy how easy it is to conceive how those two unusually large abscesses in the previous case arose, and how they grew and existed in spite of the brain being apparently completely unaffected.

² Münchener Klinische Wochenschrift, 1887, p. 19.

³ Deutsches Archiv für Klinische Medizin, 1894, vol. lv., p. 557. Kochel has gathered together in his treatise also a few of the cases recently published by Furbinger, Königsdorf, Bucklers, and Leichtenstein, under the name "primary cerebral hemorrhage," a denomination first used by Strumpell. But even these cases also have great clinical and anatomical analogies to those which should be designated chlorotic thrombosis of the cerebral sinuses. A decision with regard to this is as yet immature. The above-mentioned observation is important, as no infectious disease preceded it. As a rule it is influenza which seems to give rise to primary cerebral hemorrhage. Our microscopic observations showed no irritative phenomena, no infiltration of the vascular walls or emigration of leucocytes; the histological report corresponded completely with that of ischemic softening. So far as I know, no other microscopic observations but those of Kochel have been made, but although he found the aspect of the nervous matter in the chlorotic thrombus very like that of primary cerebral hemorrhage; our case, on the other hand, differs very considerably.

Here we have a phenomenon by no means new in nature—that which is, appears not to be, and what is false has the appearance of truth. This phenomenon reveals the state of ignorance under which we still labour with respect to the determining conditions of symptoms of cerebral disease. It is not enough, in picturing the brain to ourselves, to compare it to a keyboard as I have done above, the keys of which give out the same sound whatever the blow be which they receive; it must be added that the instrument is of so delicate a nature that the striking of a key not only produces its own sound—direct phenomena,—but can also put the other keys into vibration—indirect phenomena,—just as happens in a harp when given a sharp blow. Indeed this resonating vibration occurs even when the only key touched corresponds with a cord which has no sound (cerebral area of unknown function). From which fact it results that the vibrations of all the strings are often repeated, are very much alike, and are often the most important phenomena, not to say the only ones. Now, since from any key sufficient impulse can come to put all the other cords in vibration, the inference as to which key was struck is very difficult and not rarely impossible. I admit that this is not scientific language, but the simile is useful in such an argument to avert controversy, into which we might be led by the desire to establish the mechanism which determines the uniformity of clinical manifestations in different endocranial processes, or the diversity of these same manifestations in identical processes. Certainly one of the most important elements for the generation of cerebral symptoms is the mechanical process of compression, which may be caused in one part of the intracranial contents by a collection of pus or accumulations of blood or lymph, and in another by the growth in number and volume of cells and fibres, or the development of aneurysms or parasites. There is always one consequence, and it is this: In the limited space within the bones of the skull the pressure must be increased, a fact which will be felt all through the brain, but especially in the adjacent area and less resistant parts, such as the lymphatic sheaths and the cerebral ventricles. Consequently the blood will be at greater tension in the capillaries of the brain, the veins will become turgid and tortuous, and the lymph will break through its walls and distend the cavities of the brain. It is enough to remember the fine sensibility which distinguishes the cerebral tissue with regard to circulatory changes, to understand how this mechanical process must bring with it many analogous disorders of the brain notwithstanding the difference of the morbid processes. But it is enough also to compare the enormous compression observed in the patient's brain in the previous case with the slight degree noticed in the present one, to be convinced that the mechanical element is by no means the only cause of indirect symptoms. And as the other elements are more doubtful I have preferred to use the allegory to show the synthetic fact of the very frequent and uniform participation of the whole brain in lesions evidently limited to only a part of it. Such an elucidation of facts is calculated to represent how true it is that a certain diagnosis of chronic abscess of the brain, in the present defective state of our science, is only very rarely possible.

(To be continued.)

CASES ILLUSTRATING THE SURGERY OF THE KIDNEY.

By J. KNOWSLEY THORNTON, M.B., C.M. EDIN.,
CONSULTING SURGEON TO THE SAMARITAN FREE HOSPITAL FOR WOMEN
AND CHILDREN, NEW HOSPITAL FOR WOMEN, AND GROSVENOR
HOSPITAL FOR WOMEN.

ON April 9th, 1889, I had the honour to read before the Royal Medical and Chirurgical Society an account of my first twenty-five cases of extirpation of the kidney by abdominal section,¹ and an abstract of my paper will be found in THE LANCET.² I now propose to continue the record of my cases of nephrectomy and also to give brief notes of other interesting cases of renal surgery. I shall give a short reference to every case I have operated upon since No. 25 in the table accompanying the above paper,³ and record at greater

length the cases possessing special features of surgical or pathological interest.

CASE 26.—The patient was a young woman twenty-five years of age, suffering from advanced tubercular disease of the left kidney, with a large perinephric abscess. Dr. Broadbent kindly saw her with me, and agreed that nephrectomy offered the only chance of life, though her condition rendered the operation more than usually grave. There was no distinct history of tubercle on either side. Her father had died of Bright's disease. The mother said the patient had always been a delicate and nervous child. The urine, examined for me on three separate occasions by Mr. Malcolm, was of good specific gravity and colour and deposited urates, contained rather more albumen than the pus would account for, only about half the proper quantity of urea (she was entirely confined to bed and taking very little food), and was scanty in quantity. I thought, however, that we might fairly hope that the other kidney was capable of doing its work well. She had been really ill for two and a half years, the first symptom being frequency of micturition, six months later pain in the renal region, and pus in the urine. In the summer before I saw her she had got a chill during menstruation, and after this became rapidly worse; and in the autumn a specialist was called in and aspirated the kidney through the loin, only obtaining a very small quantity of very thick matter. The immediate result of this operation was great increase of pain and fever, with a diffuse tender swelling behind the kidney (perinephric suppuration). I operated on March 25th, and the operation was prolonged and difficult, owing to the extent and denseness of the adhesions. She did not rally well from it, but at first the kidney acted remarkably well. The day after the operation the urine was loaded with pink urates. There was some sickness on the first day and more on the second; the temperature fell quietly to 98.6° F.; but the pulse was quick and weak, and during the day the urine gradually decreased in quantity till 4 P.M., when complete suppression set in; at 5.45 P.M. she had a severe convulsion, became comatose, and died at 7.17 P.M. The temperature was 97.0°, and the pulse shortly before death was 108.

Surgically all went well. I drained the sac with a glass tube, and before death there was nothing but a little clear sweet serum from it, and in a well-doing case the tube would have been removed. I am at a loss to account for the sudden failure of the kidney, but, considering all the symptoms, I think it was a form of septicæmic poisoning, and I firmly believe that the death should be attributed rather to the aspiration and its unfortunate results than to the nephrectomy, which failed because it had not a clean field and came too late. There can be no doubt that perinephric suppuration adds enormously to the risk in these cases. The only patient in the paper referred to above (No. 20) in which this condition was present also died in about forty-eight hours, exhausted with the profuse discharge. Of course, the large cavity round the kidney, with its burrowing sinuses and ragged pus-discharging walls, must, after the operation, add greatly to the work of the remaining kidney, but I regard suppression as usually indicative of some septic element. The one kidney, already burdened with extra work, quickly fails altogether when the elimination of septic organisms and their product also falls upon it.

CASE 27.—The patient was a young married woman aged thirty years, sent to me at the Samaritan Hospital by Dr. Lawrie of Weymouth. The right kidney was much enlarged; it weighed fourteen ounces after removal and after four and a half pints of fluid had been evacuated from its interior. The fluid was dark turbid urine, which became solid on boiling with nitric acid, contained pus, renal cells, and urates, 0.972 per cent. of urea, and was of sp. gr. 1024, and faintly acid. There was nothing worthy of note in the operation or recovery, which was rapid and uninterrupted. The interest lies in the pathology of the condition. The distended kidney was first discovered in the abdomen after the birth of the first child. She had been very large, and suffered much pain in her right side during the last five weeks of gestation, and the urine was thick and albuminous. The swelling gradually disappeared, and in her next two pregnancies gave her no trouble; in her fourth pregnancy she became very large in the fourth month, and again suffered great pain in the right side; the kidney was aspirated through the loin and seven quarts of matter (*sic*) were removed. Eleven weeks later twelve quarts were removed; six weeks later another six quarts; a fortnight later the child was born, and then the tumour, which was large after the birth, gradually disappeared. The urine passed was quite clear

before the birth and very thick for a long time after. When she came into hospital she was passing about 30 oz. in the twenty-four hours. The specific gravity was high. It was thick with urates. There were no albumen, no pus, no casts, and there was a considerable tender swelling in the right loin and abdomen. At the operation the ureter was so small that I could not make it out, and it was cut and tied with the vessels. After removal the opening was found to be very minute and the tube somewhat twisted on itself. Doubtless these two conditions were at the root of all the trouble, and the case was from the first a congenital hydronephrosis, which became accentuated during the first pregnancy, and in this last pregnancy became a pyonephrosis. There was nothing in her family or personal history to throw any further light upon the case.

Most cases of hydronephrosis (not due to calculus) which I have seen appear to me to be congenital, and due to some malformation or malposition of the ureter; they are only intermittently troublesome till the distension becomes so great that the ureter is altogether blocked, or till some other disease or accident causes the formation of pus, when all the symptoms become aggravated. The condition is, however, often one of great discomfort or positive suffering to the patients from youth upwards, and is one in which they receive little sympathy, as so often the swelling disappears, and on examination there is nothing to be found to account for the patient's symptoms. The health often suffers greatly, and I am sure an earlier removal of the hydronephrotic kidney would be the proper treatment in most cases. Three patients in whom I have tried opening and draining are going about with loin fistulae, and with no prospect of cure unless they submit to a further operation.

CASE 28.—This case has been fully recorded in a paper read before the Clinical Society.

CASE 29.—The patient was in the Indian Civil Service, aged thirty-one years, and had suffered from symptoms of renal calculus for many years, and been frequently invalided home. Calculus had been diagnosed, among others, by Sir William Jenner. I first saw him in January, 1886, and, after consultation with Dr. Paul, advised him to return to India and to try once more whether he could work, as he was then in excellent health and free from any serious symptoms. His urine at that time was of normal specific gravity and colour; it had a very faint trace of albumen and pus cells, but no blood discs, no crystalline deposits, and 2.45 per cent. of urea. There was absolutely nothing to be made out by physical examination, not even any marked renal tenderness. The history began in 1873 with dull pain over the left kidney, sometimes he could neither lie, sit, nor stand with comfort. These attacks of pain recurred from time to time till 1879, when they ceased, and he began to pass urine like coffee, always after excessive eating or drinking. Travelling never brought on any attack. In 1881 he had a sharp attack of Indian fever, followed by gout in both hands and feet, and in 1883 he had another attack of fever, and in 1885 a very severe attack with hæmorrhage from the bowels and pus in the urine. The latter, he remarked, "was probably due to the stone in my kidney." I found the right kidney distinctly large and free from all tenderness; the left I could not define, and no amount of pressure over its situation or along the course of the ureter caused any discomfort. My examination produced a good deal of pus in his urine, and a few days after some specimens contained a large quantity of oxalates, some very large. He returned to India, but was very soon again out of health, and eventually in 1889 came again under my care for exploration of the kidney. I operated on June 1st, 1889, Mr. Murray giving chloroform and Mr. Malcolm assisting, Dr. Walker, who had attended him, being also present. I made a small abdominal incision over the left kidney, and found the right kidney to be large and healthy, the left sacculated and soft; there was no trace of a stone either in the kidney or the ureter, but the lower two-thirds of the latter was distended with urine to the size of a large sausage. No amount of manipulation would make this pass into the bladder. I removed the kidney, dealing separately with the vessels and ureter, and then found that a large pair of forceps ran easily through the ureter into the bladder. Evidently the obstruction to the escape of the urine was due to a curious valved and sacculated condition, which became more marked on fluid pressure from above. This condition was the only pathological one found, and must have been the cause of the gradual destruction of the

kidney, which was converted into a mere shell. The patient made a perfect and uninterrupted recovery, was shooting partridges in September before his return to India, has enjoyed the best of health since, and plays cricket and endures severe fatigue in big game hunting in India—in fact, can do everything that a strong man can do.

This case appears to belong to the same class as the preceding one—malformation of ureter, hydronephrosis, pyonephrosis, and gradual destruction of the kidney.

CASE 30.—The patient was a young man aged twenty-two, whom I first saw in consultation with Dr. Heron in June, 1889. He had also been supposed to be suffering from calculus till Sir Joseph Lister diagnosed renal tumour and suggested that I should be consulted. The history was as follows. In 1884 he had connexion with a prostitute, and had as a result some matter under the prepuce, and redness and irritation of the glans, but no urethral trouble. I mention this because a question of syphilis arose later, and he was treated for it in consequence of the condition of the glands in his groins, but I do not myself believe that he ever had syphilis. In 1886 he first noticed blood in his urine, and had pain in his left loin, never any pain in passing urine or after the act, but occasional ache in the penis, which he attributed to small clots sticking in the urethra. He had two or three attacks of very severe pain and had been laid up with one of them in an infirmary. The pain was agonising and extended down the course of the ureter and into the left testicle, and there was on one occasion almost complete suppression of urine. These attacks ended by the passage of long, red, worm-like bodies, which from his description were evidently blood casts of the ureter. He was one of a large and fairly healthy family, but his mother died from phthisis; his father, a strong old man, was alive and well. There was no history of malignant disease. Examination showed a very considerable smooth enlargement of the left kidney, with the colon crossing its lower and inner border. It was tender to touch, but not very markedly so. The patient was thin and sallow and had an anxious expression, and his face indicated a good deal of suffering. The passage of blood casts of the ureter is a very important symptom of malignant growth in the interior of the kidney, and I feared that this would prove to be the nature of the disease in this case. The diagnosis entered in my case-book was "malignant disease of the left kidney, probably intra-pelvic." I operated on June 20th, 1889, Dr. Heron being present, Mr. Murray giving chloroform, and Mr. Malcolm assisting. I made the usual Langenbuch incision over the kidney and first examined the right kidney, which was large and healthy. The left kidney was much enlarged and lobulated, and in the pelvis close to the renal vessels was a hard substance which I at first thought was a stone. I accordingly incised from the loin, and the knife plunged into a large cavity from which very free dark hæmorrhage took place. On introducing my finger I found it was a dilated calyx full of soft growth; the mass I had felt from the peritoneum was a harder mass of growth projecting into the pelvis. I now decided to remove the kidney. Enucleation was very difficult owing to the dense nature of the adhesions, and several times my finger passed through the soft outer wall into calyces full of growth, and considerable quantities of brain-like matter escaped into the capsule. I was obliged to put a pair of large Wells's forceps on to the vessels and a smaller pair on to the ureter and divide both before I could get the mass drawn down and get at the extensive and dense adhesions in the upper part of the abdomen. During the separation I suddenly heard a curious whistling noise and felt air rushing over my fingers, and knew that I had wounded the pleura. I tied the vessels and ureter separately, and pinned the latter into the lower angle of the abdominal incision. Though I could hear and feel the rush of air I could not find the wound in the pleura, which must have been a small slit. I passed a rubber drainage-tube through the loin wound into the upper part of the sac, and a glass tube into the lower part through the abdomen. The operation lasted two hours and three-quarters. The chloroform being very badly taken, owing to the patient evidently having a bad cold and cough, was a cause of much loss of time. He bore the operation well and was in very fair condition when I dressed him in the evening, but during the night the temperature rose rapidly to 103° F. and the nurse applied ice to the head. Early next morning dark brown sickness began, and in the middle of the day I washed out the stomach. There was some trouble

with the breathing during the day, and the chest was jacketed in linseed meal poultices. On the second day the expectoration was rusty, and the dark vomit began again. The patient was very restless. The temperature was 102° and the pulse 116. I again thoroughly washed out the stomach and reapplied the poultices. He passed fifty-four ounces of urine in the first twenty-four hours, with much blood in it at first; but it soon cleared. He took wine and beef-jelly freely, and the rectal injections were well absorbed. Dr. Heron examined the chest on the fourth day, and found very little action in the left lung and the heart displaced to the right side. The bowels acted well after an enema on the fifth day. Dr. Heron again examined the chest and found the heart in a better place, cardiac dulness being normal. In the evening the patient had an attack of acute pain in the left chest, and poultices were reapplied. From this time recovery was rapid and only interrupted on the twelfth day by a violent attack of pain in the abdomen from eating a lot of strawberries without my permission. There was never at any time polyuria, which is so common after nephrectomy from about the tenth day onwards. He was out driving on the twenty-eighth day and is quite well at the present time.

The growth was a soft, brain-like sarcoma (large round cells chiefly), and sprang from the lining membrane of the calyces and pelvis. The escape of much of this into the capsule during the enucleation made me anxious as to recurrence, but it is now over five years and there has been no sign of it, so I hope that he is safe. He has never been very strong, either before or since the operation, but can play cricket and lawn tennis, boat and swim, and walk well. In the early days after the operation he suffered much from flatulent distension of the colon, but this has practically ceased with care in regulating the bowels and the occasional use of a little atropia and morphia. The wound of the pleura never gave any serious trouble, and must, I think, have closed pretty quickly. There has been no flattening, and there is nothing different to be detected between the two sides with the most careful auscultation and percussion.

(To be continued.)

CONDITIONS OF THE DWELLING AS AFFECTING RECOVERY FROM MEASLES.¹

BY J. SPOTTISWOODE CAMERON, M.D., B.Sc. EDIN.,
MEDICAL OFFICER OF HEALTH, LEEDS; CONSULTING PHYSICIAN,
HUDDERSFIELD INFIRMARY, ETC.

GIVEN a greater or smaller prevalence of measles, the question as to which of the sufferers shall die and which shall recover will depend largely upon their comparative resisting power. This resisting power is doubtless dependent upon idiosyncrasy, upon age, and upon other factors. Amongst the latter the sanitary environment is probably not the least important. "Poverty, hunger, and dirt" are likely to retard, if not prevent, the recovery of those attacked, and are amongst the most potent of the causes making for death. Everyone in practice knows how much less likely a half-fed infant, brought up in a dirty house, is to recover; but it is interesting, where possible, to ascertain, and if maybe statistically, what influence house conditions themselves have in this matter. During the three years 1891, 1892, and 1893 the dwellings of some 1770 patients who suffered from measles have been examined by the ward inspectors in Leeds. Our information in the first instance was generally obtained from the death returns, but where an outbreak occurred in any district the inspector would sometimes inquire from house to house in the neighbourhood of its prevalence and ascertain what other cases existed and the conditions of the dwellings. Frequently he would obtain information from the teachers at the neighbouring schools as to absentees and visit their homes. In one or other of these ways most of the 1770 cases came upon our books. Naturally, our information having been thus gathered, it included a large number of fatal cases, 657 in all. In the same houses in which these patients

¹ Read at a meeting of the Leeds and West Riding Medical-Chirurgical Society, Jan. 11th, 1895.

died we heard of 229 who recovered. These 886 cases occurred in 627 actual dwellings—that is, an average of 1·4 per house. The remaining 884 cases, all of which, so far as is known, recovered, occurred in 547 houses—that is, again, 1·6 per house. Although these numbers are not very large, they yet afford a certain amount of material for comparison. In order to make the comparison more striking it will be convenient to regard the houses in which the 884 patients recovered as if they had been 884 houses instead of 547. Each patient lived in a house, and the condition of such house has been recorded. In this way many conditions, favourable or otherwise, which may have affected the recovery, are repeated for every measles patient exposed to their influence. The information is regarded as dealing with what has been elsewhere called “recovery houses.” In the same way the 657 deaths, which occurred in 627 actual houses, are dealt with as if there were 657 “death houses,” the 229 recoveries in these houses being for this purpose ignored. There is, however, one exception to this mode of dealing with the figures—that is, in regard to the actual density of population in the houses themselves. In obtaining the relation of houses to inmates, houses to rooms, and rooms to inmates, it has been thought better to deal only with actual houses in both cases. I will deal with this exceptional matter first.

Density of population.—In the 627 actual houses in which one or more deaths occurred there was an average of 5·98 inmates per dwelling, while in the 547 actual houses in which the 884 cases of measles recovered, without a death, the average number of inmates was 5·93. There were, therefore, rather more persons per house where death occurred than where recovery was the rule. The number of persons per house, or rather per tenement, in the whole of Leeds at the 1891 census was 4·66. The density of population in these measles houses, both where death occurred and where death did not occur, was therefore considerably in excess of the average house population of Leeds. The excess is probably even greater than the figures show, for wherever we have been able to compare the number of inhabitants enumerated in any group of houses by the census officials, and by our own private inquiry, it has always been greater in the former. The difference between 5·98 and 5·93 does not look very much, but it is close upon 1 per cent. In the actual houses in which death occurred there was an average of 3·18 rooms per house. In the 547 in which all the patients recovered the rooms averaged 3·80. When we come, therefore, to examine into the ratio between the rooms and occupants it is not surprising to find that in the 627 actual houses in which death occurred the number of persons per room was 1·88, while in the 547 in which measles did not prove fatal it was 1·56—that is to say, there were about 20 per cent. more persons per room in the former than in the latter. If we deduct a living-room from each house the number of rooms in the 627 houses in which death occurred becomes 1368, and the inmates per room become 2·7. Similarly the rooms in the 547 houses with no death become 1534, and the inmates per room 2·1, or as 9 is to 7.

Back-to-back dwellings.—I will now quit the actual houses for the death houses and recovery houses, as explained before. The 657 death houses comprised 542 which were either back to back, “salt pie,” or single houses without opening in the rear, and they included 115 death houses which had a through draught. These numbers represent 82·5 per cent. of death houses without, and 17·5 per cent. of death houses with, a through draught. The corresponding percentages for the recovery houses were 78·5 without, and 21·5 with, a through draught. These figures are altogether irrespective of other surroundings, such as, for instance, where a through house might have its back yard largely occupied by a midden privy, or where a back-to-back house might stand in a thinly populated district. Generally the larger houses in which measles occurred would be through houses. Our inspectors, however, would naturally investigate chiefly the outbreaks in populous parts, although the death houses, whether large or small, would all be visited. That is to say, while all death houses are in the list, the recovery houses would naturally be chosen from those most easily reached along with other work.

Disconnection of drains.—Of the 657 death houses 24·4 per cent. had drains which were severed entirely from the sewer, 71·2 per cent. were not severed from the sewer, and 4·4 had no drain at all. The corresponding figures for the 884 recovery houses were 27·5 disconnected, 70·2 not, and 2·3

without any sort of drain. Measles would, therefore, seem to have been more fatal in houses not properly severed from the sewer and in those which had no drain.

Closet arrangements.—In regard to the arrangement of closets I propose to divide the houses into three groups—viz., (1) those which had inside or outside waterclosets; (2) those which had the use of latrines (or trough waterclosets); and (3) those which had closets on the midden or pail system. Amongst the death-houses the watercloset system was found in 17·2 per cent., the latrine system in 38·8, and the dry—that is, the midden or pail—system in 44·0 per cent. Amongst the recovery houses those using waterclosets jumped up to 33·6 per cent., those with latrines were only 24·7 per cent., and those with one of the dry systems of refuse removal were 41·7 per cent. Measles was therefore less fatal amongst the houses with waterclosets and more fatal amongst those with latrines and middens or pails. There are of course certain fallacies about this method of computation. It has been necessary, for instance, to reduce the number of conveniences of this kind to one for each house, and a slight variation might occur with regard to the waterclosets if the computation were otherwise made, but as the difference in this respect between the death houses and the recovery houses is nearly as 17 to 34, it is probable that the possible fallacy may be safely disregarded.

In conclusion, dealing with sanitary conditions other than the question of back-to-back houses, and air space or latrine accommodation, the houses in each group may be divided as follows. First, taking all the houses to which there is a drain, in which every drain is severed from the sewer, and in which (if a watercloset exists within) the soilpipe is properly ventilated, and deducting from these all such as were found by the inspectors in a dirty condition, overcrowded (that is, having not less than three inmates per room), and all such as had drainage or other serious nuisance (such as a midden within three yards of the house), the remaining houses which might be regarded as sanitary in regard to drainage, cleanliness, &c., made up in the first, or death, group 19 (19·03) per cent. of the whole. Those having some or other of these sanitary defects (exclusive of want of through draught or existence of a midden if such were remote from the house) formed 81 per cent. (80·97). Amongst the recovery houses the corresponding percentages were as follows: in a sanitary condition 24 (24·43) per cent., and in an insanitary condition 76 (75·57) per cent. On the whole, the conclusion seems to be warranted that the fresh air provided by a through draught tended to produce recovery where measles had attacked the family, while overcrowding, dirt, and structural or other insanitary conditions assisted in bringing about a fatal result.

Leeds.

SEVEN CASES OF AMPUTATION AT THE HIP-JOINT.

By F. T. PAUL, F.R.C.S. ENG.,

SURGEON TO THE LIVERPOOL ROYAL INFIRMARY.

THE following seven cases constitute my series of secondary amputations at the hip-joint. The patients all recovered, and none of them suffered more shock than they would have done from any other major operation. This amputation would, I imagine, be more frequently put in practice in hopeless cases of hip disease were it not for its bad reputation in the way of mortality. The high death-rate is due to shock, and it is by correctly appreciating the conditions which create shock that we may hope to obtain better success. Statistics show that the mortality after amputations increases as they approach the trunk; yet after an experience of a considerable number of amputations of all kinds I have arrived at the conclusion that the severity of the shock is not at all regulated by the number of inches removed. On the other hand, it has appeared to me that when a limb has been a great source of pain and exhaustion to a child, its rapid and comparatively bloodless removal may be followed by an almost immediate improvement in the general condition. In my judgment, hæmorrhage is commonly the first factor in the causation of shock following amputation, and the second is the combined effect of the extent and duration of the tissue injury. Of course, these are often in proportion to the height of the amputation, but they are

not necessarily so. The wound is, or need be, very little larger in hip than in middle-thigh amputation, and as the latter involves division of a large bone, whilst the former can be completed without, any little inequality in the size of the wound is thus neutralised. Then, as regards duration, a hip-joint amputation may be performed in about the same time as any major amputation. If, therefore, it were conceded that neither the extent of the wound, nor the time necessary to complete the operation satisfactorily, contributed materially to the production of an undue amount of shock, there remain only the two factors of inches and hæmorrhage. The former, as I have said, seems to me to have *per se* very little effect; and if this is true the higher mortality of amputations at the hip-joint must be attributed to the greater difficulty which has been experienced in controlling the hæmorrhage. That the want of a good method has been severely felt is evidenced by the number of suggestions which have been made with a view to overcome this difficulty, and it is only because no method is so satisfactory as to be universally adopted that I mention the simple plan of fixing an Esmarch's tourniquet adopted in my cases. It has proved reliable and effectual, and in no case was there any more troublesome bleeding than in an ordinary amputation through the thigh. The operation employed was a large anterior flap cut from without inwards, disarticulation, and a shorter posterior flap cut from within outwards. The femoral artery was always tied as soon as the anterior flap had been cut, from fear of accidents, and I think this should be the rule, as half a minute's

Diagram showing simple mode of applying Esmarch's tourniquet in operations on the hip-joint.

free bleeding from the femoral artery would probably be fatal in one of these exhausted children. The mode of fixing the elastic tourniquet is almost childishly simple. Two pieces of calico bandage are placed in position, as shown in the engraving, one crossing the opposite shoulder and the other the opposite hip. The tourniquet is applied over these pieces of bandage round the innominate bone, being hitched above the crest of the ilium in front and the tuberosity of the ischium behind. Then the free ends of the bandages are carried back to the shoulder and hip and tied sufficiently tight to prevent slipping when the limb is removed. This takes off some of the elastic strain over the external iliac artery, so a roller bandage is pushed under the tourniquet at this spot to increase the pressure on the vessel. The plan described is certainly less severe than Wyeth's method with steel mattress needles, and is, I believe, equally secure; at

any rate, I have used it in all my cases and feel that I can recommend it with confidence, for I attribute the success obtained almost entirely to the absence of any appreciable loss of blood, due to the satisfactory manner in which the tourniquet controlled the vessels.

CASE 1.—A boy aged eight years was admitted in 1882 suffering from chronic hip-joint disease, for which excision had been performed in 1831. There was continued discharge and commencing lardaceous disease. He recovered well from the amputation, but when last seen, a few months subsequently, still had discharging sinuses.

CASE 2.—A girl aged eleven years was admitted with hip-joint disease in December, 1882. Excision was performed. There was extension of caries to the femur, with copious discharge and rapid emaciation, as well as marked lardaceous disease; the liver was very large, extending to the umbilicus. Amputation at the hip-joint was performed on Oct. 24th, 1883. The patient was collapsed for a short time, but soon rallied and had the usual temperature of 101° F. the same evening. She made a splendid recovery, and became very fat and strong before she left the hospital. The lardaceous disease retrogressed day by day, and at the end of three months there was not a trace of it. The reason of the better recovery in this case was that the disease was limited to the femur, for the patient was more exhausted at the time of operation than any of the others.

CASE 3.—The patient was a girl aged twelve years, who had spent most of her life in hospital on account of chronic disease of the hip-joint. She was for years in the Royal Infirmary, and then went to the Home for Incurables. From the latter institution she was sent to me by Mr. Hopper for amputation. The operation was performed on Jan. 12th, 1887, and in the course of a few months she was sufficiently well to return to the Home for Incurables, where, I am informed, she was subsequently "cured." Although she had been so long ill, the liver and spleen were only slightly enlarged.

CASE 4.—The patient, a woman aged twenty years, had a sarcoma of the knee, for which I amputated through the middle of the thigh on Jan. 29th, 1890. She returned with recurrence in the stump on June 2nd, for which she was amputated at the hip-joint on the 3rd. The temperature the same evening was 98° F. There was no shock. The temperature next evening was 98° 2". She made a rapid recovery, and was discharged well on July 9th, but ultimately died from recurrence in the lungs and other parts.

CASE 5.—The patient, a girl aged twelve years, was another old case of hip joint disease with exhaustion. After sending her to the country for three months to try to put a little fresh life into her I amputated the limb on Sept. 27th, 1892. There was very little shock. The temperature the same evening was 98° 6' F., and the next night 99° 4', whereupon it continued as before, between 98° and 100°. She was discharged in March, 1893, being able to get about, but still with some sinuses unhealed.

CASE 6.—The patient, a man aged forty years, was admitted on March 24th, 1893, for a sarcoma of the inter-muscular fascia of the thigh, the size of a small cocoanut. Amputation at the hip-joint was performed on the 25th. There was no appreciable shock. The temperature the same night was 100° F., and continued slightly above normal for several days. The wound suppurated, but he was able to go home on May 8th, and subsequently gained flesh, becoming stronger than he had been for a long time. He is still (January, 1895) free from recurrence.

CASE 7.—The patient, a boy aged eleven years, had hip and knee disease on the same side. The knee was quiet and firmly ankylosed at a right angle. The hip was discharging freely through long sinuses. He was admitted on March 21st. Amputation at the hip-joint took place on the 29th. The axillary temperature for the same evening is recorded as 96° 4' F., but he certainly did not suffer acutely from shock, as I cannot remember feeling any anxiety about him, and the subsequent progress was good. The temperature only once reached 100°—viz., on the fourth evening—and after the seventh day it was normal. On May 10th he began to get about on crutches, and on the 17th he was discharged.

Rodney-street, Liverpool.

MR. W. G. EVANS, public vaccinator to the second district of the Frome Union, has been awarded the Government grant for successful vaccination for the fifth time.

ON A MORE FREQUENT USE OF FORCEPS IN MIDWIFERY PRACTICE.¹

By WILLIAM BERRY, F.R.C.S. IREL.,

HON. MEDICAL OFFICER, ROYAL ALBERT EDWARD INFIRMARY, WIGAN.

THE idea of this paper was conceived in Liverpool at a meeting of the North of England Gynæcological Society, when a paper was read by Dr. Macfie Campbell on "A Plea for the More Frequent Use of Forceps." I thought when I went to the meeting that I had, as an ordinary general medical practitioner, kept up with the times, and had noted every advance in the obstetric art. I went prepared to criticise and be criticised, armed with statistics of twenty years' practice; but found, to my surprise, from the reader of the paper and the remarks of younger men, that I was, to use the homely phrase, "licked into a cocked hat." It is no intention of mine to argue as to why forceps should be used. The indications and rules for the application of forceps are rigidly laid down in every text-book on midwifery. Before giving the opinions of others on the use of forceps I will furnish statistics as to their use in my own practice.

First ten years, 1875-1884. No. of cases, 1246: forceps, 203; tedious (not forceps), 96; or 1 forceps case in 6.133, about 16 per cent. Now, if we add the tedious cases, which perhaps ought to have been forceps cases, we have 1 in 4.166, or about 24 per cent.

Second ten years, 1885-1894. No. of cases, 829: forceps, 133; tedious, 50; or 1 in 6.233; with tedious, 1 in 4.475.

Dr. Macfie Campbell says that he has used forceps in 29 per cent. of his total cases, and of these 50 per cent. were in primiparæ and 20 per cent. in multiparæ; that is to say, in every other primipara he found it advisable to terminate labour instrumentally, while in multiparæ he used forceps, one in five cases. Of these cases taken together one in four were long forceps cases, in the others Braithwaite's short forceps were used. The *New Zealand Medical Journal*² states that Dr. Alexander of Wellington had attended between January, 1892, and May, 1894, 170 labours. In 65 cases chloroform was given and the forceps were applied. This is a little over 39 per cent. of cases. He says the patients were saved a great deal of pain, and as they were not exhausted they made good recoveries. Dr. Macfie Campbell had stillbirths 1 in 31, or 3¼ per cent. over all his cases. He had no maternal deaths in 180 cases—that is, his last 180 cases. His maternal mortality was 1 in 177, including a labour during typhoid fever and a case of hydatids, in neither of which were forceps used. In his recent cases he finds that the proportion of forceps cases is greater than in his earlier time—namely, 37 per cent., or nearly so. His course of proceeding, as stated by himself, is as follows: "If I find on arrival that the os is undilating or not larger than a shilling I go away; if the os is larger, dilating, and the pains regular I remain, but never, or hardly ever, give chloroform at this stage. When the os is fully dilated or the membranes have given way I give chloroform. If the labour goes on regularly, well and good; but if delayed I never allow a patient to be longer than one hour and a half under chloroform without delivery. Excluding cases of disproportion, the delay in these cases is below the brim or on the perineum, and the short forceps soon terminates them and conserves the maternal strength. I have never regretted early interference, but often have delay, and have frequently felt sure that I have saved children which otherwise would have been stillborn. That, of course, is belief, not fact, which admits of proof. I have never had a perineal rupture which would have required operation. As a routine I put in a catgut stitch immediately if the fourchette, which always, or nearly always, gives way in first labours, is torn beyond the commissure." He says also: "I never use ergot before delivery, and hardly ever after, which was once my routine practice." Dr. Alexander believes that the questions how soon the forceps should be used and whether chloroform is needed when they are applied remain unsettled. He says the custom of the country has much influence, so that the medical attendant is not altogether responsible for the frequency of the employment of the forceps. Thus in Wellington, New Zealand, the patient insists on complete narcosis, so that the

pains generally disappear; after the loss of consciousness the forceps are required. Mr. Rumboll of Leeds attended 102 confinements from 1892 to October, 1894; of these, 71 were multiparæ and 31 primiparæ. Chloroform was used in 91 cases, 68 times to the surgical extent, in 23 sufficiently to deaden pain. Forceps were used 68 times, in 28 out of the 31 cases of primiparæ. Of these cases 7 had split perineum, which was stitched at the time with three sutures of silk-worm gut. All healed by first intention. In the multiparæ one case of split perineum occurred, which did not heal by first intention, and a secondary operation was performed. In five cases the child was born before his arrival. Out of the 102 cases six had a temperature above 100° F.; in three of those cases the child was born before his arrival, one was stillborn, and two cases were breech presentations. Perchloride of mercury was used for the hands of the operator and the external genitals of the patient were bathed with it; forceps were dipped in a 1 in 20 carbolic lotion, and carbolic vaseline was used as a lubricant. In most of the cases the uterus was washed out with water which had been boiled, but with no antiseptic. Out of 600 cases Mr. Rumboll had no maternal death. Dr. F. Churchill estimated the frequency of forceps cases to be among British practitioners about 1 in 171; French, 1 in 140; and German, 1 in 106; or, in a total of 985,446 cases of labour, about 1 in 115. Somewhere about 1866 Dr. Hardie of Manchester wrote a paper³ in which he advocated that after the second stage had occupied two hours labour should be terminated in the interests of mother and child by the application of forceps, as by such a procedure we prevented the mother becoming exhausted, and prevented the child in many cases from being stillborn. Since I commenced practice here I have tried to follow this plan, but have not always been successful in having my own way, the aversion of the patient to the use of instruments having to be considered. Only in a small proportion of my forceps cases have I given chloroform. Unless a good and sensible nurse is present it is not easy for one man to give chloroform and apply forceps; if a reliable nurse is at hand, no doubt she can see to the chloroform after the patient has been anaesthetised, whilst delivery with forceps takes place. When I was a student we were told a great deal about meddlesome midwifery being bad, and how dangerous it was to interfere with a natural physiological process; then we were given rules which should guide us in the application of forceps, such as os fully or almost fully dilated, membranes ruptured, and certain obstructions to the head coming down, either from fault of the mother's pelvis or the too large size of the child's head; the fault of the uterus itself getting overtired and exhausted and unable to rid itself of its burden. Roughly speaking, these were the chief indications for the use of the forceps; the sufferings of the mother were never considered, nor the time of the medical practitioner, and at the period I speak of he was supposed to watch and wait, "forsooth for labour pains," and not use any instrument to aid delivery unless the indications I have mentioned existed. The curse put on the daughters of Eve that she should bring forth in suffering and sorrow may have had something to do with the reluctance of accoucheurs to interfere, but probably the chief cause was the danger to the mother and child from the use of instruments. I have an impression—which, however, may be wrong, and it certainly cannot be proved—that a tedious case of labour terminated without artificial aid recovers sooner than a difficult forceps case. The dilatation of the soft parts never seems to be taken into consideration nowadays. The rigid perineum seems either not to exist or be forgotten. I remember when I was undergoing my final examination being asked by an old obstetrician what I would do if I had a case of rigid perineum. If I had said I would give chloroform and put on the forceps I fancy I should have got three months to do it in, but knowing that he was a gentleman with a grandmotherly feeling I told him I should foment the perineum and apply lubricants. I need not say that I have not followed this practice since, although I obtained my diploma and a certificate in midwifery.

Now have we not progressed with the progressives and gone to the other extreme? Is it correct practice, now that we have such faith in antiseptics and confidence in ourselves, to make labour as easy as this, and as soon as we can after being called to a case to give chloroform and apply forceps and deliver the child, then express the placenta, syringe out the uterus with sterilised water, swab the vagina and vulva with perchloride of mercury solution, put on a binder, straighten the

¹ A paper read before the Wigan Medical Society on Dec. 6th, 1894.

² Extract in Brit. Med. Jour., Oct. 6th, 1894.

³ Braithwaite's Retrospect.

bed, sprinkle the patient with eau de Cologne, put on our hat, take our bag, and depart? If it is so, then we have attained the some of perfection in midwifery, and we have "labour made easy" with a vengeance. The "new woman"—I mean the new midwifery woman—will have no chance of competing with us, and the "new woman" need have no dread of maternity. If this is admitted my professional brethren will endorse a line of treatment which will enable me to spend as little time as possible in the lying-in room, and I shall be in a position to defy nature's waywardness in her maintenance of our race. But first let me be just to the men who advocate this plan, and, by way of conclusion, quote the advice of Dr. Macfie Campbell—advice as well as a note of warning. He says: "In advocating this free employment of instrumental help I speak to men of experience and manipulative skill, and do not mean this for students or very young practitioners. For a young practitioner to have a mishap with a forceps case, especially as all teachers do not think alike, might be fatal to his reputation. He had better delay or get assistance until he can afford complete independence. Finally, meddling midwifery, as we were taught of old, is bad, but a policy of leaving things to nature is often one of leaving them in very bad hands." Now, if it had not been for this note of warning I should have gone on my way rejoicing that we had found at last our El Dorado in midwifery practice, that we could advertise "labour made easy," perform the work at our own time and in our own way, and give a promise to the "new woman" that maternity could be purchased without risk and without suffering.

BILATERAL FACIAL PALSY AS A SEQUENCE OF INFLUENZA.

By W. J. BARKAS, M.R.C.S. ENG., L.R.C.P. LOND.

CASES of bilateral facial palsy are very rare even when caused by injuries or in connexion with diseases of the brain or the temporal bone, or from syphilitic, gouty, &c. diatheses; but when purely uncomplicated they are very uncommon. The case I now record is one of simple neuritis of both facial nerves after their exit from the stylo-mastoid foramen unless it can be considered that influenza acts directly as an animal poison to the nerve tissues, as has been suggested by Drs. Gowers, Althaus, Ross, Bury, Sansom, and others. That the influenza may have been a direct factor in its causation I am very much inclined to believe, as my patient's brother had an attack of Bell's paralysis after influenza about a month previously. It may also be incidentally noticed here that in this case the heart's action (which previously had been slow) remained persistently somewhat rapid—a fact that further points to some of the cardiac nerves having also been affected by the influenzal poison.

The patient, a medical man thirty-six years of age, married, resides in a district nearly one hundred miles from Sydney, which is bitterly cold and bleak in winter. There is no personal history of syphilis, alcoholism, or any other diathesis, and he has always enjoyed good health. His brother had an attack of right Bell's paralysis after having been ill with influenza, as also his father twenty years ago. As the patient did not come under my observation until four days after the seizure I shall append his personal statement concerning that period: "The attack of influenza commenced about the end of June with slight pyrexia during two or three nights (nearly 100° F.), but normal in the morning, and there was no further pyrexia afterwards. There were rapid pulse, persistent pains in the head and back, and also all over the body occasionally, and total loss of appetite. All of these symptoms subsided very slowly, leaving great debility, anorexia, and heart rapidity for about four weeks. At the end of that time the appetite increased, and the night sweats during sleep, which had been very troublesome all through, began to disappear, the influenza not being sufficiently bad during this time to prevent me seeing my out-door patients. At the end of July we had some extremely severe weather, with snow and persistent gales with sleet, and the driving against these winds caused considerable discomfort to my face. On the morning of July 28th I noticed on waking stiffness and swelling of the left side of the face, and on attempting to shave found I had no power over the labial muscles. I could still whistle, and the closure of the eyelids was not complete. On the following morning I found complete facial paralysis on both sides, the face felt

stiff, and the lips hung down, the face generally being flaccid and the forehead smooth; the nerves of sensation were not affected at any time; all voluntary movements of the eyelids, lips, nostrils, cheeks, and forehead were impossible; the nostrils had fallen in; the eyes were open and exposed to dust or water when washing; eating was difficult and very slow, as the food got between the gums and the cheeks, and liquids nearly always escaped from the sides of the mouth. I thought there was an absence of taste two days before the paralysis appeared, but I am doubtful whether this was not due to the condition of the surface of the tongue, and about the same time I noticed some difficulty at the maxillary joints in mastication. There was a total absence of pain about the head or ears at any time, except what seemed like rheumatism of the muscles at the back of the head, but which was neither persistent nor severe." On the 30th he came to Sydney, when I first saw the patient. His symptoms then were similar to those mentioned in his statement, but there had been some slight improvement, as he could now lower the eyelids sufficiently to cover half the eyeball; he could also faintly twitch the lips and cheeks, and by pressing his fingers on the upper and lower lips he could speak fairly well, pronouncing even some of the labial sounds, but without that pressure he could not enunciate any words having b, f, p, m, v, u, w, y in their formation, nor could he whistle; there were no apparent movements of the facial muscles even under emotional influences, so that when one would expect to see the face wrinkle with smiles or laughter it remained an immovable mask. There was complete sensation everywhere. On firm pressure over each nerve at its exit from the foramen there was slight tenderness. Otherwise he was apparently well; he slept fairly, the appetite was good, and the tongue clean, but the bowels were rather sluggish. The heart's action, however, still remained somewhat rapid, averaging 96; but there were no marked symptoms of any cardiac lesion or any rise of temperature. He had been taking a mixture of salicylate of soda, strychnine, and digitalis. This I stopped, and ordered the following: five grains of iodide of sodium, ten grains of bromide of sodium, five minims of tincture of digitalis, fifteen minims of syrup of orange peel, to half an ounce of water—every four hours; also a smart purge and blisters behind each ear every other day. In four days there was very rapid progress towards recovery, but more so on the left side than on the right, and I then ordered the following: twenty minims of dilute hydrobromic acid, half a grain of sulphate of quinia, ten minims of tincture of strophanthus, infusion of orange peel to one ounce—every four hours; and blister on right side only. On July 11th (seventeen days after seizure) the left side of the face had almost completely recovered, and consequently the face had not now the expressionless appearance of double palsy, but resembled that of unilateral or Bell's paralysis. He could whistle fairly well, and talk without compressing the lips with his fingers. As quinine mixture caused acute gastric disturbance I returned to the iodide of sodium mixture. On Aug. 17th the patient felt drowsy; there were pains in the lumbar regions and marked supra-orbital headache. The temperature was 99° 6', the heart's action 98, and the nerves on both sides of the face near the foramen were very tender on pressure. The gastric disturbance still continuing I changed the medicine to the following: five grains of iodide of potassium, eight grains of bromide of potassium, five minims of tincture of nux vomica, ten minims of tincture of strophanthus, to half an ounce of glycerine and water—every four hours, and repeated blister on right side. The feverish symptoms disappeared by the 19th, and the right side of the face seemed to be improving, but slowly. I used a weak galvanic current, but only for a minute or two, as the right facial nerve became very tender and painful. The muscles did not respond to the current on the right side. On the 26th (thirty-one days after the attack) the patient was progressing favourably; the face when at rest appeared in a normal condition, except that the right eye was rather more staring than the left. When talking or smiling the muscles showed deficiency of action, and produced the appearance of slight right Bell's paralysis; otherwise he was well and able to go out, having the ears and adjacent parts of the face covered by thick pads. The rapid heart action still continued, but did not cause any marked disturbance. From this time he continued to progress very well. On Sept. 6th the action of the muscles on the right side was not quite perfect, but unless special attention was drawn to the fact the loss of motion would not be noticed.

Paddington, Sydney, New South Wales.

Clinical Notes :

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A WELL-MARKED CASE OF AINHUM.

By A. E. BARRATT HINE, M.R.C.S. ENG., L.R.C.P. LOND.,
SURGEON TO THE PENINSULAR AND ORIENTAL STEAM
NAVIGATION COMPANY.

A LASCAR twenty-two years of age came to the surgery of the ss. *Pekin* complaining of shooting pains in his legs and of the discomfort arising from the state of two of his toes. On examination the fourth toe of the right foot and the fifth toe of the left foot showed a well-marked constricting sulcus surrounding them, presenting the appearance shown in the accompanying sketches. (Figs. 1 and 2.) (The fifth toe of the right foot had been amputated some seven years ago, the result of an accident.) The sulcus was in each case deeper on the inner and upper surfaces than on the outer and lower.

FIG. 1.

The right foot, showing the sulcus on the fourth toe. The fifth toe had been amputated previously for injury following upon accident.

The patient could give no cause for the condition, and said it had been gradually developing for the past four or five years, but it had not troubled him until recently. Having read Dr. Manson's article on "Ainhum" in "Davidson's Tropical Diseases," I at once recognised it as a case of that disease. The distal portion of each of the affected toes was quite healthy in appearance, excepting a marked hypertrophy in the case of the fifth toe, and at the constricting rings there were no signs of any ulceration. Sensation in the affected toes was diminished, but the patient suffered severe pain at times from knocking them against anything, evidently from the nerves being gripped in the constriction. Treatment for some time was palliative,

FIG. 2.

The left foot, showing sulcus on the fifth toe.

but as the man said the pains in his legs prevented his sleeping, and the state of his toes interfered with his work (these men use their toes almost as a second set of fingers), I amputated both well behind the seat of the disease, and in a fortnight he returned to his work. I had

ventured to promise him that the pains in his legs would disappear when the toes were cut off and fortunately for my reputation among the Lascars on board such has proved to be entirely the case. These pains were evidently due to irritation of the terminal branches of the posterior tibial and muscular cutaneous nerves at the seat of constriction. On section the epidermis was seen to be dipping down quite to the bottom of the sulcus, which at its deepest parts was firmly adhesive to the tendon sheaths. The cause or nature of ainhum seems to be very obscure, and I certainly would not venture to suggest any. Dr. Manson speaks of the cases being most often found in Central Africa; it is certainly rare among the natives of India. Several medical men of long residence there who saw this case stated it to be the first they had seen. I am indebted to Mr. Owen Jones, an officer in this company, for the accompanying sketches of the case. SS. *Pekin*.

ACUTE GASTRIC PARALYSIS.

By E. GERALD MARCH, M.D. BRUX., F.R.C.S. EDIN., &c.

DEEMING the following details of a post-mortem examination I recently had the opportunity of making interesting and instructive from the point of view of diagnosis and treatment, I have ventured to put them on record in the columns of THE LANCET. The body was that of a girl twenty years of age, who had suffered all her life from epilepsy, in addition to having a strong epileptic family history.

The history of the case is as follows. I was called in one evening to see the patient after she had had a fit, which her friends described as similar to those she had had before. There was no reason to doubt that it was epileptic. She was in a state of apparent collapse, screaming with pain, which she referred to the abdomen, and incessantly retching, though she brought nothing up. There was not much to guide me about the abdomen save that it was tender. She continued in great agony and died in two hours. On opening the abdomen I found the stomach enormously distended, occupying quite half of the whole abdomen and burrowing behind the heart, which was displaced markedly forwards. Except shape it reminded me of a volvulus of the sigmoid; it contained about two pints of dark liquid almost without odour; the mucous coat was covered with tough mucus, but otherwise it was not much changed and did not suggest a history of long catarrh. The other organs were healthy.

This case seems to me to illustrate the importance of opening the abdomen in all sudden cases of collapse, obviously abdominal (the patient would, I think, have been able to withstand the effects of an anæsthetic when I first saw her), and had this been done her life would probably have been saved.

HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo nocendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.* lib. iv. Proœmium.

ST. THOMAS'S HOSPITAL.

A CASE OF TRAUMATIC INTRA-PERITONEAL HÆMORRHAGE
WITHOUT EXTERNAL WOUND; HÆMATOTHORAX;
RECOVERY; REMARKS.

(Under the care of Mr. W. H. BATTLE.)

CASES such as the following are rare even in the wards of our large hospitals, and we consider the publication of the one given here, although it was mentioned in the discussion at the last meeting of the Clinical Society of London, will prove of interest to a large circle of our readers. Sir Spencer Wells once said: "Abdominal surgery, though not without claims to the credit of having done good service to humanity, must still be looked upon as a branch of our science and art which,

still important, calls for continued search for truth and for constant efforts to improve methods of practice from every surgical standpoint." There are, perhaps, few departments in which we require more knowledge than in that of abdominal injury, especially when there has been no wound of the soft parts and life is threatened by "internal hæmorrhage." It is, however, one in which there is but little to guide us, and a perusal of much of the literature on the subject causes surprise that the clinical notes of most of the cases are so incomplete. In by far the larger number, even of recent date, the state of the abdomen as to the presence or absence of dullness on percussion, or other signs which might give an estimate of the amount of free fluid in the peritoneal cavity, is not given. The general symptoms of hæmorrhage are mentioned, and then we are told that a large quantity of blood was found at the operation, and occasionally surprise is expressed at the large amount discovered. In Mr. Robson's case,¹ recently brought to the notice of the Clinical Society of London, where recovery followed operation, the presence and extent of dullness as indicating the amount of effused blood are noted, but only about two pints were removed at the operation. His patient was a boy, so also was Dr. McBurney's patient.² In the latter the injury was caused by a fall across a railway line; this was followed by profound shock and pain in the back. Eight hours later, when operation was performed, there was also flatulent distension of the abdomen with dullness in the flanks, but the shock was lessening. About a quart of blood was removed from the peritoneum, extravasation had occurred in the colon and omentum, and a branch of the pancreatico-duodenal artery was found to have been ruptured; it was still bleeding and was secured by a ligature. In the case of a boy twelve years of age, published by Mr. Page,³ the injury was also caused by a fall across a line of rails. No source for the large loss of blood which followed could be found at the operation; the symptoms, however, pointed to the spleen, and at the necropsy it was found to have been lacerated. Doubt has been expressed regarding the possibility of the onset of a peritonitis as a result of hæmorrhage into the peritoneum. From his experiments on peritonitis, related to the sixty-second Congress of German Naturalists, Orth⁴ came to the conclusion that pure blood in considerable quantities was sufficient to set up peritonitis, not so much from the presence of bacteria as from the development of some fibrin ferment. The subject is too large, however, for us to deal with it in this department of THE LANCET. We give references below to which those who wish to do so can refer.⁵ The following account is taken from the notes of Mr. Dickson, the house surgeon, and Mr. Warner, dresser to the case.

A schoolboy aged twelve was admitted to St. Thomas's Hospital on Sept. 21st, 1894, suffering from shock and pain in the abdomen. After leaving school in the morning he was playing leap-frog when he missed the boy over whom he was jumping and fell on his face on the asphalt pavement of the school-ground. He walked home with assistance, but was sick after getting there. The bowels acted soon, and he passed a good quantity of urine. He was admitted to hospital about four hours after the accident. When examined in the casualty department he was found to be in a collapsed condition, and was very pale and cold, the pulse being slow and weak. A little brandy was given him, and when he rallied he complained of pain in the abdomen, but nothing abnormal could be felt. One of the incisor teeth of the upper jaw had been broken, and the boy was bleeding from his nose. When examined soon afterwards in bed the abdomen offered some resistance to palpation, and there was dullness on percussion in the left flank and hypochondriac region. The temperature was 97.2° F. Hot bottles and hot blankets were applied. Mr. Battle saw him at 6 P.M. He was then lying on his left side; he presented a white face and had dilated pupils, but no expression of pain or anxiety; he kept very quiet. The lips were paler than natural, but not blanched; the surface of the arms and face was cold. The tongue was moist, but somewhat pale. He made no

complaint of pain, but when asked he said that his stomach hurt him. The abdomen moved with respiration and the walls were flaccid, rather "sagging" towards the bed; there was no tenderness anywhere. The dullness of the liver was not increased; there was dullness extending from the left flank up to the left linea semilunaris, changing with position. The pulse was feeble and at times could hardly be felt. He was very thirsty. He had vomited since admission, but there was no special tendency to vomit. At 10 P.M. a catheter had been passed into the bladder, but no urine was drawn off; later about half an ounce was passed, but it contained neither blood nor albumen. The pulse was a little stronger, the collapse had improved but very slightly, and the extremities were still very cold. At 11 P.M. there had been some increase in the amount of dullness, which reached the right linea semilunaris. At 12 midnight the general aspect of pallor continued with thirst, but the amount of fluid in the abdomen was apparently not increasing, or was doing so very slowly. The general condition had improved; his arms and face were warm. The temperature was 98° and the pulse 96. On Sept. 22nd it was noted that during the night he had passed about ten ounces of urine loaded with urates. His extremities were warm and the cheeks slightly flushed. He complained of a little pain in the abdomen, but was unable to localise it. During the night he had taken small quantities of water. At 8 A.M. the temperature was 97.6° and at 12 midnight 100.2°. The condition of the abdomen remained as before. On the 23rd there was less evidence of fluid in the abdomen. The pulse was 100. He complained of pain in the left shoulder and clavicular region on breathing. The morning temperature was 99.2° and in the evening it was 100.2°; the pulse was 110. On the 24th he was still complaining of pain in the left side of the chest and was suffering much from dyspnoea, the *alae nasi* working rapidly. The respirations were 40 and the pulse 120. Dr. Box examined him and reported that there was apparently consolidation of the lower lobe of the left lung with fluid in the pleura. Albumose was present in large quantity in the urine. The evening temperature was 101.8°. On the 25th it was reported that the signs were as before, but there was no albumose in the urine. The pulse was 120, the respiration was 40, and the temperature was in the morning 101.2° and in the evening 102.2°; the pulse was 125. He was complaining of headache. The bowels acted after a simple enema. On the 26th, when lying on his back, there was slight dullness in the right flank, and the dullness on the left side reached to a line drawn vertically upwards from the anterior superior iliac spine. The respirations were 40, whilst the temperature was in the morning 101.4° and in the evening 102.2°. On the 28th the patient was feeling much better; the temperature was 99.4° and the pulse 120. The left pleura was aspirated and fourteen ounces of fluid of dark-red colour were withdrawn, being alkaline in reaction and containing red and white blood corpuscles. On the 29th he was without pain. The temperature was 98.4° and the pulse 80. There was dullness over the lower part of the thorax on the left side and slight dullness in the left flank. He went to the Swanley Convalescent Home on Oct. 10th. He was still pallid, but otherwise gave no evidence of anything abnormal. The temperature was normal or subnormal after the 29th.

Remarks by Mr. BATTLE.—When I first saw the patient he was suffering from severe shock, and it was not possible to gauge the exact extent to which the fall alone was responsible for this. In hospital practice cases of severe shock are frequently seen after abdominal injury even when the local evidence of damage is comparatively slight. There was here a complication—namely, that of effusion into the peritoneum—which suggested that much of the patient's serious condition might be dependent on internal bleeding, and it was difficult at once to estimate the gravity of this symptom. When first examined by me at 6 P.M. the condition was one to cause anxiety, but the more important symptoms of hæmorrhage were not combined with those of shock; he had vomited but little, was very thirsty, and complained of a dry mouth, but was lying quietly on his left side, and was in no way excitable or restless. The fluid in the peritoneum slowly increased, but without addition to the general symptoms, until about 12 midnight, when there was no longer necessity for immediate interference as the effusion was not increasing. The presence of free fluid in the peritoneal cavity within a few hours after an injury suggests either escape of urine, the result of a ruptured bladder, or hæmorrhage. It was necessary to exclude the former in this case, for at the time of the accident the patient's bladder had not

been emptied for some hours, and was probably distended. He could not tell us if he had passed urine since, nor was there anyone who knew; however, the introduction of a catheter showed that the bladder was intact. Free hæmorrhage into the peritoneum without external wound after traumatism is most likely dependent upon laceration of the liver, and such lacerations, especially if of small size, are very difficult to diagnose, sometimes indeed impossible. Rupture of a healthy spleen is almost unknown at this age. Laceration of the mesentery suggested itself, or laceration of the omentum, and of these the former is the more likely to tear. There was a complete absence of symptoms of ruptured liver or spleen, and the small amount of abdominal pain, the slight vomiting, and the absence of rigidity of the abdominal wall made me regard the case as probably one of slight rupture of the mesentery without injury to the intestine. Abdominal section should, I think, be performed if the shock from which the patient is suffering is considerable and the amount of blood in the peritoneum large, or if the shock, whatever its degree, is increasing in spite of the employment of the usual remedies, and continued escape of blood into the peritoneum is taking place. When there is no evidence that the source of the blood is a rupture of one of the viscera, it is permissible to make a longer delay. Here, also, there should be distinct evidence of increasing effusion, and it is not always necessary to search for the bleeding point, although it is desirable that such should be secured if found easily. It is not easy to measure the amount of fluid in the peritoneal cavity and its rate of increase unless the patient be examined always on the side. In this position the pelvis is emptied to a great extent, and it is easy to mark the line of advancing dullness due to the effusion on the abdominal wall and estimate the rapidity of its escape from the lesion. It has on former occasions been pointed out that excessive shock should not be considered as contraindicating operation, as by means of saline infusion the patient may be brought into a condition for the necessary procedures when it is a question of vital importance that the hæmorrhage should be arrested by surgical means. I do not think that the question of operation is settled when the hæmorrhage has stopped, though there is generally rapid absorption of the effusion, for a quantity of blood in the peritoneum may cause inflammation from the changes which ensue. One of the first signs which may be called unfavourable will then be a commencing distension of the abdomen, and this should be regarded as an important indication for interference. The constant desire of the boy to lie on the left side was difficult of explanation, until the onset of the pneumonia made it evident that there had been injury to the left side of the chest in addition to the injury of the abdomen. There were no symptoms of laceration of the lung when he was admitted, but the presence of the hæmatothorax and the later inflammatory attack make it evident that such must have occurred, although probably of limited extent.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Varieties of Intestinal Obstruction dependent on Gall-stones, with a series of cases.

AN ordinary meeting of this society was held on Jan. 22nd, the President, Mr. HUTCHINSON, F.R.S., being in the chair.

Mr. MAYO ROBSON read a paper on the Varieties of Intestinal Obstruction dependent on Gall-stones. He remarked that the usually accepted form of obstruction was only one of four varieties of intestinal obstruction depending on gall-stones, which he proposed to classify as follows:—1. The form dependent on local peritonitis in the region of the gall-bladder, leading to paralysis of the bowel. Two illustrative cases were related, both of which yielded to general treatment without operation. 2. Volvulus of the small intestine dependent either on the violence of the colic caused by an attack of cholelithiasis or on the contortions induced by the passage of a large concretion through the small intestine. Two cases were related in which Mr. Robson performed laparotomy and untwisted the volvulus, recovery following in each case. 3. Mechanical obstruction due to the

passage of a large concretion through the small intestine. Two instances were given in which enterotomy with removal of the concretion was followed by recovery. 4. Obstruction depending on adhesions or on stricture, the result of past gall-stone attacks, or of healing fistulae. As this form was specific only in the antecedent cause instances were only referred to and not related, since cases of this kind could be more fully discussed in a paper dealing with the subject generally. Mr. ROBSON, in answer to questions addressed to members of the staff or to the registrars of a number of large metropolitan and provincial hospitals, had received communications from institutions representing about 80,000 patients, and out of this number only four cases of intestinal obstruction from gall-stones had been recorded during the past twelve months, proving that this form of obstruction is far from common, and all the four cases coming under the third form described in his paper seem to prove that it is the commonest.

Mr. ARBUTHNOT LANE, in connexion with the first class of cases, quoted an instance in which he had operated for acute intestinal obstruction in which he found the distended gall-bladder pressing upon the colon and duodenum.

Mr. ARTHUR BARKER cited a case seen by him post mortem in which copious diarrhoea preceded for some time the vomiting which ushered in the fatal termination. The obstruction was in the lower part of the ileum, and the case was recorded in the Transactions of the Clinical Society about sixteen years ago. The only other case with which he was familiar was one operated upon by Mr. Thomas Smith, who cut into the bowel and removed the stone, the patient making an excellent recovery. He did not approve of needling the stone through the bowel wall, and considered that shyness about opening either the large or small bowel was carried a great deal too far. He then recounted a case of volvulus, the cause of which was obscure, upon which he had operated with a good result. He had thought since that this might be due to gall-stones, and asked Mr. Robson whether in these cases he had met with effusion into the peritoneal cavity, it being a point of great practical and pathological importance whether the bowel might be so long twisted as to allow the passage of septic matter through its walls.

Mr. EDGAR WILLETT said that in the St. Bartholomew's Hospital Museum there was preserved a gall-stone four inches in circumference impacted in intestine; also the sutured portion from which a stone had been removed in a patient who subsequently died from a second obstruction. The specimen showed excellent union along the line of suture.

Mr. J. JACKSON CLARK said that out of 800 post-mortem examinations he could recall only one in which he had seen a gall-stone impacted in the small intestine. It was two inches long and half an inch across.

Mr. F. S. EVE referred to one case of gall-stone impacted in the large intestine in the Museum of the Royal College of Surgeons of England, and suggested that some of the cases cited might have recovered if left alone. He quoted 20 cases collected by Mr. Treves which had not been operated upon, of which 6 recovered and 14 died. Of 26 cases which had been operated on 10 recovered and 16 died. Up to 1889, of 8 cases operated upon 7 died; whereas subsequently to that date, of 18 cases operated upon 9 recovered, showing a very great improvement in recent years.

Mr. CROFT said cases of obstruction from gall stone were very rare. His own observations had not led him to differ from the opinion expressed.

The PRESIDENT said he was disappointed that no attempt had been made by Mr. Robson to collate the successful cases in recent years. For himself he would say that up to the present time one half the cases died after operation, and he did not think the subject had advanced to the point at which it could be said that "delay in such a case is criminal." Even in cases where death was threatening he thought the chances of recovery were about equal to those of a fatal issue if operation was decided against. In his own experience of obstruction a large number of cases exhibiting very severe symptoms improved spontaneously, and large gall-stones could be shown which had passed the bowel without assistance. He quoted one case which on the ninth day when apparently in *extremis* was relieved by the passage of the stone; while one operated on under similar conditions died. Another objection to the rule in favour of operating in these cases was that in the hands of less experienced surgeons the mortality would probably be greatly in excess of what it was at present. The third class of cases

he thought did not support the contention in favour of operating. There was one important class which had not been alluded to—viz., cases in which a gall-stone remained for months in the intestine, giving rise to repeated attacks of obstruction. He mentioned two cases of this kind, both of which recovered, passing the stone without assistance. He further stated that he had never yet in the post-mortem room seen a case where an impacted stone had caused death.

Mr. MAYO ROBSON, in reply, said that the statement to which the President had taken exception only applied to a particular instance, and was not intended for a general rule. That desperate cases of impaction did recover he freely admitted, but thought that some cases which died might have been saved if operated upon before tympanites appeared. With regard to the second class, in which volvulus occurred, recovery was scarcely possible without operation. He thought that statistics prior to the last two years could not be accepted as giving any idea of results as they might be obtained now, and still less as representing what he anticipated in the near future. He quite agreed that were the operation performed by all surgeons as a routine treatment there might be an increased mortality. In answer to Mr. Lane, he thought volvulus was due to the violence of intestinal contraction when a large stone was passing or obstructing the bowel. He had operated on four cases, in two of which a stone was obstructing the small intestine and was associated with some peritoneal effusion.

HUNTERIAN SOCIETY.

The Operative Treatment of Perityphlitis.

AN ordinary meeting of this society was held at the London Institution on Jan. 9th, Mr. CHARTERS J. SYMONDS, President, being in the chair.

Mr. SYMONDS read a paper entitled "The Operative Treatment of Perityphlitis." The paper was founded upon twenty-three cases which had come under his care for surgical treatment. Questions of surgical import only were dealt with, and the important question, When should operation be undertaken? Mr. Symonds stated that the cases were necessarily divided into two groups: (1) those in which operation had been performed in the quiescent stage for relapsing typhlitis, and (2) those in the acute suppurating condition. The first group included six cases. The following are briefly the notes of each. Case A is reported in full in the Clinical Society's Transactions for 1885. The patient had had several attacks of colic during the six months before the removal by operation of a calculus from a cavity outside the appendix. The peritoneal cavity was not opened. Mr. Symonds now exhibited the calculus removed in July, 1883, and stated his belief that this was the first case of perityphlitis operated upon in the quiescent stage. The calculus was composed of calcium phosphate and fecal matter, and the question was whether such a calculus could have formed in six months. In two other of the six cases a calculus was also found on operation. In one, Case B, there had been symptoms of colic for two years. The calculus rested in a cavity outside the appendix and presented a laminated appearance similar to that of Case A. In Case C a calculus of similar size and form was removed from a cavity in the iliac fossa. In this case the cecum was adherent to the abdominal walls, and a fecal fistula resulted from sloughing of the intestinal walls and still persisted. The patient had suffered from typhoid fever one year and enteritis three months before admission. Before operation there was a small area of exquisite tenderness in the lower part of the right rectus muscle. The symptoms in these three cases were of three, six, and twenty-four months' duration respectively from the first attack. Case D, a female, had had two attacks, the first twelve and the second two months before admission, with an ill-defined right iliac swelling and pain on walking. The abdomen was opened, the appendix removed, and perfect recovery resulted. Case E, a girl aged eight, had had a first attack five years ago, when three years of age. With quiet and care she had no second attack till 1893. The patient came under Mr. Symonds' care during a third attack, when a tumour could be felt at the brim of the pelvis. The appendix at the operation was found to be hanging down into the pelvis and adherent to the rectum. It was removed, and the patient did well. Case F was a student who had had two attacks and in whom at operation a mass of white lymph was found adherent to the

iliac muscle and to two coils of ileum. The appendix and omentum were removed, and recovery resulted. Thus in these six cases four had had two attacks, one had had great pain and inability to work after a first attack, and in one the attacks had been frequent. Mr. Symonds would ask the questions—Ought we to operate after one attack, even if severe? Ought we to advise operation after a second attack? And, thirdly, if in suppurating cases the appendix could not be found, should the peritoneal cavity be opened if necessary in order to find and remove the appendix? He next detailed the method of closure of the divided appendix. Operation had been performed in seventeen acute cases. He stated it was important to estimate the initial severity. He considered that if the attack was not very severe or very sudden the prognosis was good so long as the swelling continued firm. Many cases recovered from the first and from the second attack. Mr. Symonds drew attention to the fact that the quantity of pus was in no way proportionate to the amount of swelling, and narrated one of his cases where the swelling was enormous, reaching above the umbilicus, and contained only one drachm of foul pus. The usual symptoms were sudden onset of pain, with or without sickness, or diarrhoea, with or without pain, with or without sickness, and with subsequent development of tumour. Case G, a female, experienced sudden pain in the right hypochondriac and inguinal regions one month after confinement. The temperature varied between 99° and 102° F. On the tenth day there was a well-defined swelling in the right inguinal region, with hectic symptoms. An incision yielded one ounce of pus, and an entire detached appendix, contained in a large cavity. Mr. Symonds said that five out of the twenty-three cases presented hectic temperature with anorexia and gradual development of the swelling. Of these five cases all but one recovered, and in that case the abscess ruptured on the thirteenth day. This patient was at first not very acutely ill, but was suddenly taken with severe pain and diarrhoea and collapse. Mr. Symonds advised operation where a tumour existed which continued to increase in spite of rest, and where the temperature rose and the tumour continued to increase in size. In another group of cases there might be an abscess in an abnormal position. The notes were read of a case where, with violent abdominal pain and tenderness, there appeared on the fifth day a small tender swelling in the cæcal region, which was demonstrated by operation to be an abscess between the ileum and cæcum. He next referred to a fourth group of cases where, with abdominal distension and septic pyrexia, no tumour was palpable. He pointed out the great value of the presence of slight œdema over the loin as an indication of the presence of deep-seated suppuration. In two cases a large abscess had been completely masked by the abdominal tympanites. He therefore advised operation where the symptoms were severe and persisted if the abdomen was tympanitic. As to the justifiability of operation during the early stages of the disease, Mr. Symonds pointed out that in two of his cases operation had been performed twenty-two and twenty-nine hours after the onset of symptoms. In one purulent peritonitis was found and death resulted. The other was admitted into hospital in a state of collapse, and operation revealed a localised abscess, which was drained with good result. Mr. Symonds considered that the danger of operation was much increased by the removal of the appendix when an abscess existed. In none of his cases of abscess was the appendix searched for.

Mr. COTMAN asked the President to what extent he was in the habit of pre-circling opium in these cases, and stated his opinion that opium merely masked the symptoms.

Dr. FORTESCUE FOX asked whether Mr. Symonds considered it possible that a distended appendix might discharge itself into the cæcum and so the abscess be discharged per anum, and narrated a case which supported this hypothesis.

Dr. F. J. SMITH said he had never yet seen a calculus in an appendix vermiformis at all resembling the one shown. He considered that the sudden onset of abdominal pain with vomiting and iliac tumour was an absolutely certain sign of pus and compelled operation.

Sir HUGH BEEVOY said he had seen six cases where sudden pain, vomiting, and tumour had all been present and the patients were all living although no operation had been performed.

Mr. SYMONDS said that in his opinion the less opium given the better. In a few cases he advised five grains of Dover's powder to be taken three times daily. He could not explain

the rapid subsidence of the tumour in Dr. Fortescue Fox's case. He firmly believed that every case which supplicated never recurred.

HARVEIAN SOCIETY OF LONDON.

Presidential Address: Evolution in Treatment from 1831 to 1895. (A Sketch.)

A MEETING of this society was held on Jan. 17th, when Mr. G. EASTES delivered the following address.

[After alluding to the vast changes that had taken place in the metropolis since the year of the foundation of the Harveian Society (1831), Mr. Eastes continued:]

"All branches of medicine have participated in our recent strides in knowledge, but it is impossible for me to survey more than a minute part of so wide a domain, and I select the division of prevention and treatment of disease for two reasons. It is perhaps the department of medical work that most nearly concerns the world in general; it is also the goal whither the studies and researches of all departments of medicine lead. But even here I must restrict myself to a portion only of the subject—viz., the evolution in some of the opinions held as to treatment which has occurred within the life-time of our society. In 1831 preventive medicine, except in the case of vaccination, was non-existent. Anyone ill of an infectious disease remained at home; neighbours ran in promiscuously to visit the sick person, and the disease was spread broadcast. Nurses and medical practitioners went from case to case without attempt to avoid the spread of infection. But to-day notification, isolation, and disinfection are rigidly enforced, and the sanitary defects of an infected house are remedied. Everyone knows, too, that preventable diseases may be spread by infected water or milk, every food or drink is judged, and filters themselves are not above suspicion. 'Quis custodiet ipsos custodes?' As a practical policy, too, personal cleanliness is displacing the vexatious quarantine of the past in other lands besides our own, which in sanitary matters has pioneered humanity; though it was not until after the horrors of cholera in England in 1849, and those of the Crimean winter campaign in 1855, that much progress was made even here. One consequence of all this preventive activity has been the well-known decrease in the zymotic death-rate of England and Wales, which from an average of 3.46 in the twenty years 1846–66 fell to 2.43 in the following twenty years. This is a decrease of 30 per cent., though the general death-rate fell only 3 per cent. in the same period. Since 1886, too, the decline in the zymotic death-rate has been accentuated; but a similar result obtains wherever preventive measures are adopted. In India, for example, 'whereas in 1865 not one single town had a supply of pure water, in 1894 nearly all the largest cities and cantonments had well-planned waterworks, completed or in progress,' with the result 'that the death-rate among the British troops has been reduced from 69 to 15 per 1000.' This beneficial change may be partly 'attributed to more rational methods of medical treatment and to improved nursing,' but doubtless is chiefly due to lessened prevalence of epidemic diseases brought about by better sanitation. Treatment has undergone a development since 1831 so vast that it may almost be described as a revolution. 'Fas est et ab hoste doceri'; practitioners saw that patients recovered under treatment by infinitesimal doses, and therefore naturally concluded that recovery would equally ensue with no medication at all, but with simple nursing and careful dieting. This view reached its climax when Gull and Sutton, before the days of salicin and its derivatives, treated acute rheumatism with strict nursing and dieting and the administration of peppermint-water as a placebo. The pendulum of treatment for this particular disease thus swung from over-medication to no medication at all; since then I believe it has reverted to the happy mean between the two extremes. There is, however, another side to the question: Do we now unduly neglect the heroic remedies of the past—venesection, for example? I fear that my esteemed friend Dr. Hare—who with Sir John Erichsen¹ was our president

in 1847–48, and both of whom we may congratulate on their present vigour, as well as the latter on his recently-acquired honours,—I fear that Dr. Hare considers *laissez faire* is too much the order of the day. In 'good remedies out of fashion' he graphically describes the care of a gentleman who, with commencing general bronchitis and overtaxed and distended right heart—clearly an extreme case—dies without any attempt at relief by venesection. But this is just the case in which all modern books of treatment urge the 'letting of blood,' and against such treatment there is no law. There was, too, fifty or sixty years ago, less recognition than in the present day of the immense control exerted by mind over matter, of the intellectual and other powers of the brain over the body. This view has been constantly insisted upon in this society; never more happily or thoroughly than by Dr. Goodhart in his Harveian Lectures on 'Modern Neuroses,' or by Mr. Herbert Page in his recent admirable lectures on 'Some Disorders of Nervous Function due to Injury and Shock.' Some patients may be, as it were, coaxed, but cannot be driven to health. He is a wise practitioner who acts upon that principle. Another distinguishing feature of modern treatment is its definiteness in aim and precision of application, qualities that have grown slowly but surely as knowledge generally has advanced, but which, in the case of surgery, have been fostered by the introduction and adoption of anaesthetics and antiseptics. On the wonderful rôle played by these two nineteenth-century developments I need not dilate; their efficacy and far-reaching effects are seen on every side, their praise is in all mouths. They have completely revolutionised our practice, especially in the direction of transferring to the domain of surgery cases that thirty years ago were never seen in surgical wards. The serous cavities are opened and their contents examined; diseased parts or even entire organs, such as kidney, ovaries, and uterus, are removed; calculi and tumours taken from the deepest organs or cavities and ulcerated patches of stomach or intestines excised; whilst ligation of the carotid artery for ingravescent apoplexy has lately been practised with success. Truly the physicians must look to their laurels, since that 'hinterland' of disease always hitherto recognised as being within their 'sphere of influence' is undergoing appropriation by an advancing victorious power. One chief element of success, especially in many of these severe abdominal operations, is a point which seems sometimes to be overlooked, but was much emphasised by Mr. Bryant a few years since in his Harveian Lectures—viz., to operate directly the operation is recognised as necessary, and not allow the case to drift and thereby become irremediable."

[After discussing the effects of such discoveries as the anæsthetic power of chloroform and the antiseptic influences of certain drugs, Mr. Eastes continued:]

"But not even to anaesthetics and antiseptics combined is due all the precision of modern treatment. I believe a very large part of its progress may be traced to the teachings of Mr. John Hilton. It is a delight to me to make this statement here, because to Mr. Hilton's philosophical instruction and common-sense views of disease I, in common with other Guy's men of my day, have been indebted for much of any insight into illness that may have accompanied us through life, and for much of the pleasure which our work has in consequence brought to us. And we feel deeply indebted to Mr. Jacobson for the charming biographical notice of our great teacher which he has lately published. Mr. Hilton, I believe, first taught systematically the true significance of pain and its interpretation, and placed the principle of treatment of diseased parts by physiological rest on a basis which, since it is founded on the general laws of physiology in health and disease, will be as enduring as treatment itself. The only valid objection I ever heard made to this principle has been when it had been continued too long, and adhesions (as in the case of joints that had been inflamed) had formed. Of its immense use in many cases, surgical or medical, all of us might doubtless quote instances. I have here notes of a surgical case, but have not time to read it. For a medical instance of the value of physiological rest in the treatment of suitable cases, one might cite a case of pericarditis, where lessening of the rate of cardiac beats is essential. As Dr. Sibson pointed out, a reduction of the heart's action by 14 beats in the minute (a reduction attainable in many cases by change from the sitting to the recumbent posture) is equal in twenty-four hours to a diminution of fully 20,000 beats of the heart, and is itself a wonderful relief to the overburdened organ. I now pass to the final stage of my theme, and propose to indicate briefly the effects to the public and to the

¹ Mr. Eastes read a letter from Sir J. E. Erichsen containing the following paragraph: "I remember perfectly well having been President of the society in conjunction with Dr. Hare about the year 1847–48—I may state that there were always two presidents in those days: one medical, one surgical—and bringing to one of the meetings of the society a bottle of chloroform, which had then just been introduced into surgical practice as an anæsthetic, and was then, I believe, called the 'terchloride of formyle,' or by some equally barbarous name."

profession respectively of the progress that treatment has undergone. To the public it has been advantageous in every way, in consequence of the incidence of illness being less frequent, its accompanying pain and sorrow mitigated, duration shortened, and results less disastrous. Amongst these results is a lowered death-rate, especially from infectious diseases, which notoriously cut off in their youth or prime those who, with life before them, are amongst the most valuable items of a population. Upon the profession, in this country at any rate, the effects of the steady progress have been many and far-reaching, and are divisible into three classes, affecting us—(1) in our preparation for the conflict with disease, (2) whilst engaged in that conflict, and (3) in the results thus accruing to us. With more to learn and examinations ever increasing in severity, the intellectual status of members of the profession generally has arisen and is rising. The unskilled 'tinker of deteriorated human pots and pans' of past days has become the cultured 'wise physician skilled our wounds to heal' of to-day. The widening sphere of science and art has, however, become too extensive for any single mind to grasp it thoroughly in all directions, and is largely accountable for the division of labour, the specialising that now flourishes everywhere. The rapid growth of this tendency is well shown by the fact that when the British Medical Association met in 1833 in Bristol in the second year of its existence its whole business was transacted in one general meeting. But last year, at the meeting in the same city, the papers and discussions were divided amongst ten sections, whilst for the scientific work of the approaching meeting in London fourteen sections have been provided, and there are, I know, those who desire even that number to be increased.

"One point in reference to modern progress I would much emphasise—viz., that our increasing mastery over disease gives added zest to work, and the more frequent recovery of patients augments much our 'pleasures of life.' And although there is on one side a lessened number of cases of illness and lessened average length of illness—which remark applies both to medicine and surgery—yet other cases that formerly died at an early stage of disease, or after accident, now pass through an illness to health, so that our work is possibly not diminished, but merely displaced. It is not, I opine, from improvements in treatment, but from other causes, especially overcrowding of our ranks and consequent over-competition for practice, from which the profession as a body suffers. But, even were it otherwise, were our means of livelihood actually restricted by the very advances in our art that we ourselves have made, yet we must remember that the self-sacrificing 'struggle for the life of others' has in no branch of human labour been more apparent than in the ranks of medicine, nor here has it ever shone more brightly than at the present moment. May the same generous spirit continue through all time to animate those who practise the divine art of healing."

The new President, Sir JOHN WILLIAMS, Bart., was then inducted into the chair by Mr. Eastes and he declared the conversazione opened. The rooms were most tastefully decorated and Mr. Oppenheimer's valuable collection of Roman and Etruscan antiquities, including Pompeian surgical instruments, was on view. There were also several hundred medical and surgical books published previously to the present century and a great number of exquisite photographs of British and foreign health resorts, all kindly lent by members and friends of the society, of whom about 300 were present during the evening.

The following are the officers for the ensuing year: President: Sir John Williams, Bart. Vice-Presidents: Mr. Rayley Owen, Mr. D'Arcy Power. Dr. W. Hull, Dr. E. Clifford Beale. Treasurer: Mr. H. Cripps Lawrence. Hon. secretaries: Mr. Peyton Beale, Dr. Cagney. Council: Dr. Boxall, Mr. Henry Davis, Mr. G. Eastes, Dr. Charles Gross, Mr. W. F. Hazel, Mr. S. Harbutt, Mr. Henry Juler, Mr. Howard Marsh, Mr. Malcolm Morris, Mr. E. W. Roughton, Dr. J. E. Squire, and Dr. Samuel West.

PLYMOUTH MEDICAL SOCIETY.

Glaucoma.

A MEETING of this society was held on Dec. 29th, 1894.

Mr. J. ELLIOT SQUARE (hon. treasurer) read a paper on Glaucoma. He pointed out the serious nature of this disease, which frequently went unrecognised until treatment was of

little avail, often under the impression that the disease was cataract, and, therefore, not requiring immediate operation. He urged the necessity of every practitioner receiving some training in ophthalmology so as to recognise this disease early. He paid a tribute to von Helmholtz and von Graefe, and cited the latter's views on the subject, more especially as to the cupping of the disc. Paracentesis of the anterior chamber (Mackenzie) and iridectomy (von Graefe) were discussed and the pathology of the disease gone into, three varieties of cupping of the disc being described. Three forms of the disease were mentioned: primary or acute, simple or chronic, and secondary glaucoma. Eserine with or without cocaine to relieve the prodromal symptoms and an early and ample iridectomy were strongly urged, if possible in an upward direction to obtain a cosmetic result. In eyes blind from chronic glaucoma in elderly people Mr. Square recommended excision of the globe. To illustrate his remarks he demonstrated two cases of glaucoma on which he had performed iridectomy with excellent results.

Charcot's Disease.—Hydrocephalic Brain.—Radical Cure of Left Inguinal Hernia.—Malignant Disease of the Oesophagus.—Exhibition of Specimens.

A clinical evening was held in the library on Jan. 16th, Mr. SQUARE (President) being in the chair.

Mr. WOOLLCOMBE showed a man forty-two years of age with well-marked Charcot's Disease of the Right Knee-joint. Fourteen years ago he fell and developed synovitis, which got well and remained so until six months ago, when the right knee began to slowly enlarge, accompanied by anasarca of the same leg. The tibia was partially dislocated backwards on the femoral condyles, and so accounting for the oedema of the leg. Many of the symptoms of tabes dorsalis were well marked, but there were no crises. Suggestions for treatment were invited.

Mr. WOOLLCOMBE also exhibited the Brain of a Hydrocephalic Child three months old. The child was born with a spina bifida, which was tapped, injected, and disappeared within a few days of birth, followed a month later by enlargement of the head; the lower limbs remained contracted and undeveloped. The occipital bone was trephined three weeks ago to the right of the external protuberance, and thirteen ounces of fluid were drawn off and a small drain introduced. Continuous drainage was kept up, but the child died suddenly at the end of the third week. Post mortem there was no meningitis, and the posterior horn of the right lateral ventricle was found to have been tapped.

Mr. LUCY brought forward a case of Radical Cure of a Left Inguinal Hernia in a man sixty-seven years of age. The operation was performed a year ago at the close of herniotomy for strangulation, and an excellent result was obtained by Mitchell Banks' method. Six weeks' rest in bed were enforced, and the patient now wore a light double truss, chiefly to keep up a reducible rupture on the opposite side.

Mr. BULTEEL exhibited a Malignant Growth—probably a Scirrhous arising from a Bartholin's gland—which he had removed from the vulva of a multipara forty-eight years of age. There were no enlarged glands.

Mr. WHITEFORD mentioned a case of Malignant Disease of the Oesophagus opposite the cricoid cartilage, with enlarged glands along the greater curvature of the stomach, and asked if this sequence were usual.

Mr. BRENTON showed a Salivary Calculus, the size of a large pea, which he had removed from the duct of the left sublingual gland of a man fifty-four years of age.

PATHOLOGICAL SOCIETY OF MANCHESTER.

Pathological Changes in Chronic Rheumatism and Chronic Gout in the Hands.—Exhibition of Specimens.

A MEETING of this society was held on Wednesday, Jan. 16th, Professor SHERIDAN DELÉPINE, M.B., President, being in the chair.

Dr. E. S. REYNOLDS mentioned some points of difference in the Pathological Changes found in the hands in cases of Chronic Rheumatism and Chronic Rheumatoid Arthritis (classed together), as compared with those found in the hands in Chronic Gout. In chronic rheumatic conditions, as a rule, the lesions are found in symmetrical joints to an equal extent, and the deformities produced are similar, though the last

is not always the case. In chronic gout, on the contrary, the changes in the hands are found in asymmetrical joints to an extent differing much on the two sides, the resulting deformities being totally different. These points were illustrated by a series of lantern slides.

Mr. J. B. WOLSTENHOLME showed microscopic specimens from a case of Biliary Cirrhosis in a horse, the condition having presented no symptoms during life. He also showed a horse's stomach studded with the larvæ of *Oestrus equi*.—Dr. A. T. WILKINSON showed a specimen of Epithelial Carcinoma taken from the bladder of a man aged sixty-two years, who died from independent cardiac disease. There were pain and hæmorrhage for sixteen days before death, but prior to this no symptoms were present. The growth infiltrated the bladder walls, especially at the fundus, and there was also a large tuberos growth projecting into the organ. There were no secondary growths in any other part. The points of interest in the case were the wide extent of the growth consistent with clinical latency; the fact that infiltrating and non-ulcerating primary carcinoma in hollow organs not normally sensitive often fails to produce pain; the sudden and serious hæmorrhage owing to the superficial vascularity, which appeared to be a superadded element; and the absence of any decided cachexia, the disease occurring in an organ in which absorption is at a minimum, and diffusion of the growth rarely occurs at an early age.—Dr. SOUTHAM showed a specimen of Perforating Ulcer of the Cecum from a man aged sixty-seven years who for some months had suffered from symptoms of incomplete intestinal obstruction. Shortly after admission into hospital death took place very suddenly, and at the necropsy a stercoral ulcer was found on the posterior wall of the cæcum, with a small perforation at its centre. The appendix was healthy, but the cæcum and colon were distended with hardened feces, apparently due to atony of the bowel, for no cause of obstruction was present below.—Professor SHERIDAN DELAFINE showed a culture of a Chromogenic Bacillus (non-pathogenic) isolated from the Manchester water.—Dr. HELME showed an Ovarian Cyst.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Relation between Death from Measles and House Conditions.—The Disruption of Impacted Biliary Calculi.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Jan. 11th, Dr. A. G. BARRS being in the chair.

Dr. SPOTTISWOODE CAMERON read a paper on the Relation between Death from Measles and House Conditions, which is printed in our present issue.—Dr. CHURTON, in discussing the paper, remarked that he had for many years been observing the influence of insanitary conditions on the course of diseases, and referred to notes of fifty instances where houses demonstrated to be in an insanitary condition had contributed cases of various ailments to the different charitable institutions of the town, and in which such contributions had ceased on the houses being put in a satisfactory condition.—Mr. TEALE referred to the influence of insanitary conditions on puerperal and scarlet fevers, which in his opinion were formerly much more fatal.—Mr. WOODCOCK expressed his opinion very strongly, and from personal experience, that the sanitary conditions prevailing in back-to-back houses were much more satisfactory than those prevailing in "through" houses occupied by people of the same social scale, largely on the ground that in the latter the front door was habitually kept shut and the front room used only on very special occasions.—Dr. CHADWICK gave Mr. Woodcock his cordial support, and stated that hitherto the comparisons between the sanitary conditions of back-to-back and through houses had been stultified by the relative poverty of those who lived in the former.—Dr. HELLIER and Dr. BARRS also took part in the discussion.

Mr. T. PRIDGIN TEALE read a paper on the Disruption of Impacted Biliary Calculi, including three cases in which a gall-stone in the common duct was broken up by the needle. After speaking of various methods adopted by himself and others in dealing with calculi in the cystic duct three cases were related in which a gall-stone of firm consistence, obstructing the common duct and causing jaundice, was

broken up by means of an acupuncture needle. The first case was that of a man aged sixty-two who had been jaundiced for several months, and with some intermission for twelve months. At the end of six weeks jaundice had disappeared and he was well. The second case was that of a woman aged thirty-eight who had been deeply jaundiced for two months and with absence of bile from the evacuations for three months. An extremely hard calculus was broken up by the needle with great difficulty. She died on the third day. In the third case a calculus broken up by the needle did not pass down into the bowel but upwards into the gall-bladder, whence the fragments were washed out by the syringe over a period of three weeks. Jaundice persisted and yet about three ounces of bile escaped daily through the opening in the gall-bladder. The patient recovered her health and nutrition although the jaundice persisted.—Dr. BARRS spoke of the difficulty of making a diagnosis in some cases and referred to the case of a man he had seen with jaundice due to a distended gall-bladder. The patient was operated on and died soon after. At the necropsy no definite cause was found for the symptoms.—Dr. CHURTON thought severe pain was more often associated with calculus in the cystic duct than in the common duct. He spoke of the value of small doses of pilocarpine for the relief of the irritation of the skin associated with jaundice; this had been a prominent symptom in Mr. Teale's third case before the operation.—Mr. LITTLEWOOD thought the methods of crushing a stone with the fingers or the forceps outside the ducts would be easier and not more risky than needling. He showed a case under the care of Dr. Churton, in which he had done this a month ago for an impacted stone in the cystic duct.—Mr. CANT (Lincoln) spoke of the great density of some biliary calculi, and related a case in which he had attempted to break up a biliary calculus in the intestine by means of a needle and had failed. It was removed by incising the bowel. The patient did well for a week and then died rather suddenly. No necropsy could be obtained. He thought probably the peritoneal adhesions had given way, and referred to Mr. Greig Smith's recent paper on the weakness of some of these adhesions. He had operated in cases with well-marked symptoms in which he could find nothing to account for the biliary obstruction. The patients had, however, been relieved since the operation. He thought Mr. Teale's method of needling was a safer and better procedure than crushing from outside the ducts with forceps.—Mr. TEALE replied.

The following cases, pathological specimens, &c., were shown:—

Mr. WARD: Case of Actinomycosis after one month's treatment with Potassium Iodide.

Dr. BARRS: Case of Locomotor Ataxia due to Peripheral Neuritis.

Dr. CHADWICK and Mr. LITTLEWOOD: Malignant Disease of Oesophagus which perforated into the Trachea a few hours after Gastrostomy.

Mr. LITTLEWOOD: (1) Tongue removed for Epithelioma (patient and specimen shown); (2) Lower End of Femur from a case of Acute Infective Osteo-myelitis.

Dr. GORDON SHARP: Ununited Fracture of the Femur (specimen).

Dr. CHURTON: Sections of Normal Kidney from a case of Acute Anasarca and Oedema of Lungs (child).

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

Exhibition of Cases.—Aortic Aneurysm.—Resection of the Intestine.

THE fourth meeting of the society was held on Jan. 16th, Dr. CLOUSTON, President, being in the chair.

Dr. LUNDIE showed a patient after operation for Perforating Gastric Ulcer.—Mr. CAIRD showed a patient after removal of the Vermiform Appendix.—Dr. BYROM BRAMWELL showed two boys suffering from Progressive Pseudo-hypertrophic Muscular Paralysis. Two girls in the same family had been shown last year.—Dr. MACGILLIVRAY showed a patient after operation for Empyema of the Antrum of Highmore and a case of Partial Excision of the Elbow-joint by Subperiosteal removal of the Condyles.—Dr. NORMAN WALKER showed a woman with typical Lichen of the Forearm.—Mr. CATHCART showed three Gelatine Casts of Warts

in Female Genitals which he believed to be due to a special contagious form of poison not necessarily associated with gonorrhoea. A well-marked Copaliba Rash was also illustrated with photographs and drawings.—Dr. BRAMWELL showed a man presenting the typical physiognomy of Congenital Syphilis.

Dr. ALEXANDER BRUCE read notes on an Aneurysm which had perforated into the Superior Vena Cava. The patient had been admitted to the Royal Infirmary suffering from cyanosis and breathlessness. He had suffered from a cough for some time, and a month before admission "caught cold" and one morning he noticed a blueness of the face and difficulty in breathing. On admission his face was found to be swollen and greatly cyanosed; the neck was cedematous on both sides. The jugulars were full, but did not pulsate. The skin of the thorax was of a leaden colour with distended venules and cedematous. The left side of the thorax was free from lividity, but was cedematous. The abdominal wall seemed quite normal. The upper extremities were cedematous. Dyspnoea was marked. The respiration was 32 and the pulse 104. The area of impaired percussion sound over the precordia extended from the mammary line on the right side at the level of the third rib to the mammary line on the left at the level of the fourth rib. Over the heart a peculiar continuous murmur, with a somewhat musical "swishing" sound, was heard most intense during the systole and dying away during the diastole, and heard best at the level of the third costal cartilage. At the apex both first and second sounds appeared to be normal. There was a slight impairment of the percussion sound below the spine of the scapula on the right side. After admission the patient had a very severe attack of dyspnoea. The oedema and lividity of the chest increased, though the legs remained free from oedema. The point of maximum intensity of the murmur shifted a rib higher. The patient gradually became worse. Edema of the glottis supervened, and in spite of treatment he died eighteen days after admission. Post mortem there was marked oedema of the chest wall. The aorta showed an aneurysmal dilatation extending from the valves to the origin of the innominate artery. The aneurysm projected forward and to the right, pushing the vena cava backwards. Its size was about half that of the average closed fist. On the right and posterior aspects were two small perforations into the superior vena cava. The superior vena cava and left innominate vein were firmly bound down to the aneurysm. The superior vena cava was narrowed, partly from pressure of the aneurysm and partly from organisation in the walls over about a fourth of the circumference, the walls being adherent. The heart was almost normal. From the first there had been little doubt about the diagnosis. The localised oedema suggested at once obstruction to the superior vena cava. The nature of the obstruction was rendered evident by the existence of the murmur, with its peculiar continuous character and its limitation to the sternum and right side of thorax. The perforations into the vena cava probably took place, the one before admission and the other immediately before the alteration in the point of differential maximum intensity and the murmur.—Dr. BYROM BRAMWELL and Dr. G. A. GIBSON having spoken, Dr. BRUCE replied.

Mr. CAIRD read notes on Resection of the Intestine. He drew attention to the conditions under which the surgeon had to deal with obstruction and tumours of the intestine, dividing them into a series in which the symptoms were urgent from tendency to gangrene, and those in which there was no urgency. In the first series he advocated generally, when tumours were encountered, the formation of an artificial anus, and a secondary operation within ten days to deal with the growth. In strangulated hernia, when the elongated necrotic area lay opposite the mesentery and did not involve more than one-third of the circumference of the gut even when perforation existed, he advised the invagination of the dead area. He had treated four cases successfully by this method. Were half or the whole of the gut involved then resection and end to end continuous suturing was the best plan. He advised a free removal especially of the congested central extremity of the gut, and described the method employed in two successful cases. In obstruction by gall-stone he advocated longitudinal incision, removal, and suture. He had had two such cases, which, however, proved fatal apart from the local condition and operation. In the second series of cases he strongly advocated early diagnostic incision when doubtful, and described a case where ten years ago he had removed an extensive epithelial tumour of the

ileo-caecal valve, with three inches of ileum and six inches of colon, the patient still enjoying perfect health.—Mr. CATHCART congratulated Mr. CAIRD on the success of his abdominal cases. In gangrenous hernia he thought resection far more satisfactory than artificial anus.—Mr. STILES described the procedure at Professor Kocher's clinic.—Mr. WALLACE spoke, and Mr. CAIRD replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Series of 100 Cataract Extractions.—Method of Restoring the Lower Lip after Excision for Cancer.

A MEETING of this section was held on Jan. 4th, Mr. W. THORNLEY STOKER, President, being in the chair.

Mr. J. B. STORY read a paper upon a series of 100 operations for Senile Cataract, including both complicated and uncomplicated cases. Only two eyes out of the 100 were lost—both by wound infection. In 8 cases the vision obtained was less than $\frac{1}{2}$, and 3 cases, though surgically successful, remained with only perception of light owing to pre-existing disease of other portions of the eye. In 42 cases simple extraction was done (without iridectomy). Forty-six combined extractions were done, and 12 extractions after preliminary iridectomy. Mr. Story dwelt upon the importance of thorough asepsis as the principal factor in determining the result of a cataract extraction, and stated that his experience as yet was not sufficient to enable him to decide upon the comparative merits of the simple operation and the extraction combined with iridectomy. The section advocated by Mr. Story was the 3 mm. flap as proposed by De Wecker, and first performed in this country by Mr. Story in 1879.—Mr. SWANZY thanked Mr. Story for his paper. He had done 270 operations, not taking into account traumatic cataracts, and had only had two cases of suppuration, both of which had occurred in the first 100 cases. The method of antiseptics employed was as follows. The eyelids were everted and the eyes thoroughly washed with 1 in 10,000 corrosive sublimate. Any solutions, as those of atropine or eserine, were made up with the same solution. The instruments were sterilised by boiling and then put into a bath of weak carbolic lotion, from which they were taken. The dressings were also dipped in corrosive sublimate solution and oil silk put over them to prevent them drying.—Mr. STORY, in reply, said that the antiseptics employed by Mr. Swanzy were much the same as his except that corrosive sublimate solution was used instead of boiled boric acid solution.

Mr. JOHN LENTAIGNE read a paper describing a method of restoring the Lower Lip and the Soft Parts covering the Chin which he had employed in four cases of advanced Cancer of these parts, with exceptionally satisfactory results from an aesthetic point of view, and, so far as he had been able to learn, without any recurrence of disease. The operation consisted in removing the diseased tissues in a square piece between vertical incisions—one on each side and a horizontal incision below parallel to the free border of the lip. These three incisions must be carried through perfectly sound tissues only, and at least a quarter of an inch of apparently sound tissue should everywhere lie between them and the nearest margin of the diseased mass. In this way the position of the incisions would vary with the extent of the disease. The flap which was to form the new lip was then taken from the tissues under the chin and on the upper part of the front of the neck by prolonging the two vertical incisions downwards as far as might be necessary and dissecting off the quadrilateral flap between them. This was then drawn upwards to form the new lip and front of the chin and was fixed *in situ* by wire sutures, a drainage-tube having first been inserted in the middle line at the centre of the lowest part of the flap so as to allow of free drainage from the pouch under the chin. The head should be bent towards the sternum and fixed in that position until the flap became firmly adherent in its new position. When preparing his paper he had learned for the first time that the principle of the operation was not new; it had been long before introduced by the great French surgeon Chopart, and was described in many French text-books on operative surgery as the "procédé de Chopart," but there was no mention of it, or anything like it, in any English work that he had seen.—

The PRESIDENT said that he had never seen a better restoration of the lip than the one exhibited, which was done by Mr. Lentaigne by this method. He would, however, hardly accept it as a universal method.—Mr. LENTAIGNE said he did not mean that this operation should supersede all others. It was only required where the whole lower lip was diseased. The material used for dressing was gauze and wood wool, which was changed as soon as it was soaked, and then a flannel bandage with starch, which fixed the part.

SECTION OF MEDICINE.

Case of Locomotor Ataxia due to Injury.—Small-pox.—Small-pox Temperatures.

A meeting of this section was held on Friday, Jan. 11th, Dr. WALTER G. SMITH, President, being in the chair.

Dr. CRAIG exhibited a patient and read a short paper on Locomotor Ataxia due to Injury.

Dr. O'CARROLL read a paper on the Diagnosis and Prognosis of Small-pox, based upon the experience of cases treated in the Hardwicke Hospital during the present epidemic in Dublin and the much smaller epidemic of 1887-8.

Dr. H. C. DRURY, in his contribution on Some Small-pox Temperatures, exhibited a series of temperature charts of variola cases. He divided them into three classes—1. Those with primary and distinct secondary fever. 2. Those in which the initial fever was continued into a period of febrile state, of longer or shorter duration, but without any distinctive character. 3. Those in which the high initial temperature, lasting three or four days, was the only one seen. He pointed out that, from a large number of observations, he was unable to draw any conclusions from the temperature as to the severity of the rash, general symptoms, or length of time till convalescence was complete, as all three classes of temperature were seen in unvaccinated as well as vaccinated cases, mild and exceedingly severe or even fatal cases, or cases in which the rash was confluent or discrete, copious or slight in amount, also in cases that could be considered free from infection in three weeks, or in others that would require from two to three months.—Dr. TWEEDY said he thought that a good many cases of small-pox were passed off as chicken-pox. He had seen a child aged seven years covered with a discrete vesicular eruption, most of the vesicles being umbilicated. He was told that there were several children in a neighbouring house who had been similarly affected, and had run about all the time. He was in doubt as to whether it was a case of variola or varicella, but concluded that it was the former, and sent the case to hospital.—Mr. BURGESS said that in 1887 he was asked to see a case which another medical man first considered to be rheumatic fever and then scarlet fever. When he saw it he could not make up his mind what it was, but he waited for a couple of days, and by that time there was a distinct rash. This was the first case of the epidemic of 1887.—Dr. DAY said that in the early diagnosis between small-pox and chicken-pox the eruption of the throat was an important point. In the former a papule might be present on the soft or hard palate or on the tongue. In chicken-pox it was a vesicle. A woman had been treated in the Fever Hospital, Cork-street, for small-pox who was six months pregnant and yet did not abort. Several children were treated for both scarlet fever and small-pox at the same time. The acute cases of scarlet fever seemed to have escaped. He said he believed that chicken-pox occurred in adults and also that the vesicles were umbilicated.—Mr. Horne, Dr. Parsons, Dr. J. W. Moore, Mr. A. N. Montgomery, Dr. Smith, and Dr. O'Carroll having also spoken, Dr. Drury replied.

HOSPITAL SATURDAY FUND.—The board of delegates of the Hospital Saturday Fund held a special meeting on Jan. 19th, at which it was reported that the total receipts for the past year were rather over £20,000. It was resolved that £17,600 be divided among 165 institutions as follows:—To 30 general hospitals, £6202; to 63 special hospitals, £6392; to 35 dispensaries, £1063; to 17 convalescent homes, £1497; to 18 miscellaneous institutions, £2151. A sum of £95 was awarded to the Chelsea Hospital for Women, but was not to be paid over until the managing body of the Hospital Saturday Fund were satisfied that the reforms specified in the official report had been carried out. In like manner a sum of £63 was awarded to the Queen's Jubilee Hospital, to be paid after the refutation of various charges made against that hospital.

Reviews and Notices of Books.

A Text-book of the Diseases of Women. By HENRY J. GARRIGUES, A.M., M.D., Professor of Obstetrics in the New York Post-graduate Medical School and Hospital, &c. Containing 310 engravings and coloured plates. London: Henry Kimpton. 1894.

THE author has aimed at writing a practical work, and he has therefore endeavoured as far as possible to avoid theoretical discussions, and he has treated the pathology of the subject very briefly. The object kept more especially in view has been to teach the reader how to make a diagnosis and how to treat the different diseases. We cannot see that any apology is needed for devoting special chapters to hæmorrhage and leucorrhœa, though the author expressly anticipates some adverse criticism for doing so. Indeed, in a work of a practical character there is a decided advantage in the arrangement he has adopted. There are so many morbid conditions peculiar to women in which the discharge of blood, other than that occurring normally during menstruation, is a significant symptom, that it is no fault to give considerable space to its discussion; we should rather think that it has here been scarcely as fully treated as it deserves to be. We may observe, by the way, that the extreme shortness of some of the so-called chapters is a remarkable feature of the book. Thus, chapters of half a page or two-thirds of a page occur more than once. The chapter on Metrorrhagia consists of less than seven lines. In the chapter on Dysmenorrhœa we see that the obstructive theory still finds favour, as we read that "the cervical canal may be too narrow, especially at the internal or external os (stenosis)"; and, again, it is stated that "the uterus may be so bent that the crookedness of its canal opposes a barrier to the free outflow of the blood." In speaking of the treatment of menorrhagia it is recommended that if the use of vaginal douches of hot water fail, liquor ferri chloridi may be added to the water. We scarcely see how vaginal douches containing perchloride of iron can be efficacious in the treatment of uterine hæmorrhage. For the repair of the various kinds of laceration of the perineum three operations are described, some one of which the author thinks will be found suited for any case. They are Tait's flap-splitting operation, a modified form of Hegar's colpo-perineorrhaphy, and Emmet's operation. We observe that in one of the figures describing the second of these operations the lettering has been left out, and the description is therefore more or less difficult to understand. The author considers Tait's operation to be by far the most expeditious perineorrhaphy, and that it results in the formation of a thick and broad beam between the anus and vulva. In speaking of the treatment for hæmatometra and hæmatocolpos we find that after making an opening washing out of the uterus is recommended. The general opinion in this country is that it is better to leave the fluid to drain away entirely without assistance. Operative interference for fibroids should, in the author's opinion, only be resorted to in cases where Apostoli's treatment has been tried unsuccessfully. Many would consider that the prognosis of an operation undertaken under these conditions was much graver than if performed without any preliminary disturbance (and possibly infection) of the endometrium. In the description of carcinoma of the cervix we find it stated that "often the mucus membrane of the body [of the uterus] is affected at an early date in cases of carcinoma of the cervix." So far from this "often" being the case, we should say it is so rare that many good English authorities doubt its occurrence. We are, of course, speaking of the disease at an early stage of its progress. It seems a pity to confuse carcinoma of the body of the uterus with carcinoma of the cervix. The natural history of the two diseases is very different; but in speaking of the age at

which carcinoma of the uterus may be expected, the author simply states that "carcinoma of the uterus is a disease of advanced age." We think in a book intended partly for students it would have been advisable to emphasise the fact that cancer of the cervix is not at all uncommon in relatively young women. It is interesting to see that, according to the statistics of Charleston, cancer of the uterus is about as common among the black as among the white population, which is contrary to the general impression. In speaking of the prognosis the author is undoubtedly mistaken in teaching that even the most radical treatment effects only quite exceptionally a permanent cure, and that it is even doubtful if it prolongs life. He does not seem familiar with some of the English statistics on this subject, which go to show that if the disease is treated radically before it has reached too advanced a stage "permanent cure," if by that is meant many years without recurrence, is not in such cases at all exceptional, either in cancer of the body or cancer of the cervix. We suppose that we must take it that Dr. Garrigues' book offers us a fair picture of American gynaecology at the present time. If that is so, while gladly acknowledging the advances made by American workers in various parts of the subject, we think there is a considerable field for reform in the direction of attaching less importance to the presence of slight displacements or to doubtful stenosis at the internal or external os; and it would be something gained if the formidable two-bladed dilator (p. 153) used for dilatation or "divulsion" of the cervix could be relegated to the limbo of obsolete instruments. We wonder if the author has seen a note by Auvarod on perforation of the uterus by the curette, in which he showed that as a rule the curette merely discovered a rent in the uterus caused by the previous use of the dilator in question.

LIBRARY TABLE.

Practical Lectures in Dermatology. By C. W. CUTLER, M.S., M.D., Professor of Dermatology, University of Vermont. New York: G. P. Putnam's Sons. 1894.—The author tells us that he has published these lectures in response to the request of the students to whom they were delivered. There being only fourteen lectures, he has restricted himself to "those diseases of the skin which every physician in general practice should be able to diagnose and to treat in an intelligent manner." He also tells us that they are prepared from stenographic notes, which may account for the style being colloquial, but he also aims at being humorous. While this is doubtless pardonable as a means of attracting the attention of students during the delivery of a lecture, elaborate jokes, such as that on Elisha's baldness and bear's grease, are but poor reading, and take up a good deal of space which might have been better employed. The lectures contain necessarily much that is true without being new, and the information given, though sound on the whole, is rather scanty, even for the 230 pages to which the author has restricted himself. While the lectures may have been useful to the students for whom they were intended, they are too sketchy, we think, to prove of much value to the more experienced reader. The work concludes with a reprint of Jackson's well-known "Dermatological Don'ts," to which Dr. Cutler (still in humorous vein, it is to be hoped) adds the admonition not to omit to purchase his own work on Diagnosis!

Asthma and Chronic Bronchitis. By JOHN C. THOROWGOOD, M.D., F.R.C.P. Lond. London: Baillière, Tindall, and Cox. 1894.—This monograph is practically a revised and much extended edition of the author's Lettsomian Lectures, which gave in concise and practical form his experiences upon asthma. The subject is one which has great interest,

physiological as well as clinical, and, above all, therapeutical. It has been the field of many arguments and hypotheses, but that the cause of the asthmatic paroxysm is bronchiolar spasm, although often contested, is the theory that best accords with the facts of its occurrence, with its known relationships to other affections and with the action of remedies upon it. This view, so ably maintained by Hyde Salter in the monograph which remains to this day the most interesting and the most erudite work on the subject, is that adopted by Dr. Thorowgood, who, however, has not omitted to review other explanations or to refer to some of the relationships of the affection which have been brought into prominence since Hyde Salter wrote. Chief amongst these additions stand the writings of Schmiegelow and others upon the association of asthma with nasal polypi and other nasal affections. That there is a definite relationship between them is certain, but the tendency to magnify it beyond reason has, we fear, been the source of disappointment to many a sufferer, besides leading to much unnecessary local treatment of the nasal mucous membrane. The author of this work does not fall into such an error. He views the subject from the wider standpoint of the general physician, and has succeeded in producing a book which exhibits sound judgment upon the problems of the disease, besides containing much valuable advice upon the management of its different forms.

A Healthy Home. By FRANCIS VACHER, F.R.C.S. Edin., County Medical Officer for Cheshire. London: William Rider and Son, Limited. 1894.—This book will be welcomed by the numerous class who desire to consult some practical and trustworthy guide in matters of house construction and domestic drainage and water-supply. At the outset the author assumes that the reader contemplates the erection of a small house, and accordingly provides plans, sections, elevations, and descriptions of various styles of such a building, ranging from a labourer's cottage to a small villa residence having a rental of about £40 a year. In the opening chapters questions of site, soil, aspect, building materials, and construction are discussed at considerable length. Much of this is, of course, inapplicable to the case of the dweller in a city or of a purchaser of an existing house, and probably some would prefer a curtailment of the early chapters and an extension of those which treat of warming, lighting, ventilation, hot and cold water supply, and sanitary requisites. In like manner one of the chapters ("How to keep the House Clean") condescends to such minutiae as the proper method of washing plates and cleaning knives and forks, instead of which many heads of houses would probably rather have advice in the selection of kitchen ranges and other cooking apparatus, the setting of wash-house boilers, and the clearing of drains which have become choked. Unfortunately there is no reference whatever to the explosions of circulating kitchen boilers, which are such a frequent cause of serious disaster during frosty weather. On p. 131 there is a caution against exposing the pipes to frost, but the reality of the danger deserves more emphatic treatment. The author, however, presents a large amount of information in a convenient form, and the majority of readers will find in the book much that is new to them and of real practical value.

First Lessons in Hand and Eye Training, or Manual Work for Boys and Girls. By GUSTAV KALB, of the Leipzig Lehrerbildungsanstalt (Training College for Teachers). Translated by W. G. FIELD, M.A. London: O. Newmann and Co. 1894.—*Manual Training made serviceable to the School.* By Dr. WOLDEMAR GOETZE, Director of the Leipzig Lehrerbildungsanstalt. Translated by W. G. FIELD, M.A. London: O. Newmann and Co. 1894.—For many years past protests have been made in various quarters that modern popular education is too literary in its methods and aims, and that children whose vocation in life will undoubtedly be manual

labour of some kind or other find themselves on leaving school unnecessarily conversant with grammatical subtleties, essay-writing, algebra, and so forth. Of course, instruction in such subjects is an admirable thing in itself, but the time bestowed and the mental bias temporarily imparted are clearly anomalous in the case of a very large proportion of the pupils at an elementary school. In such learners the development of the practical and mechanical faculties is a prime necessity, and the two volumes under consideration will be found very useful aids by teachers engaged in such work. The "Hand and Eye Training" begins with Fröbel's "building box" of bricks and cubes, suitable for children of six or seven years of age, and continues the instruction by numerous devices in folded and plaited paper, modelling in plastiline or clay, and outlining of geometrical solids, until the method of making simple Christmas-tree ornaments is taught. Cardboard boxes and baskets and small wooden articles come next in order, and the volume concludes with easy examples of work for the fret-saw and chip-carving. "Manual Training" is a more advanced work than the last mentioned. It commences with cardboard as a material, and passes on to articles made of wood, sheet metal, and wire. Most of the objects on which the pupils are employed serve for illustrating elementary physics, and among the concluding ones is a simple electro-motor. The general plan and arrangement of the volumes are excellent.

Précis Iconographique d'Anatomie Normale de l'Œil. ("Globe Oculaire et Nerf Optique.") Par le Dr. ROCHE-DUVIGNEAUD. pp. 136. Paris: Société d'Éditions Scientifiques. 1895.—This brochure is a complement to the ordinary descriptions of the anatomy of the eye contained in the text-books, and is, in fact, a résumé of the author's own researches in little out-of-the-way bits and corners of the eye and its appendages. A drawing is given in each case, from his own preparation, which serves to illustrate the observations he has made. Commencing with transverse and longitudinal sections of the optic nerve, which contain nothing worthy of special notice, he proceeds to give a section and an account of the pupillary region, several sections and an account of the ciliary region, transverse vertical sections of the anterior portion of the ciliary processes, of the angle of the iris, of the choroid, of the iris, of the retina, and of embryonic eyes, which last are perhaps the best in the book. We notice nothing particularly new or striking, but the work is conscientiously done. The author observes, correctly enough, that the ciliary processes are not so much folds as laminae; he accepts a dilator iridis muscle, but observes that the muscle fibres are quite identical with those of unstriated muscle elsewhere. The suspensory ligament of the lens is not a membrane, but a series of fibres. He comments on the extreme thinness of the walls of the choroidal veins. The division of the choroid into layers is inaccurate. He makes no remark upon the glands of Nicti, Collins, and others in the ciliary processes.

JOURNALS AND REVIEWS.

The Journal of Physiology. Edited by MICHAEL FOSTER, F.R.S., and J. N. LANGLEY, F.R.S. Vol. xvii., No. 5. Dec. 15th, 1894.—The memoirs contained in this part are 1. The Time Relations of the Voluntary Tetanus in Man, with a Plate by Dr. David Fraser Harris. 2. On the Response of the Chick Before and After Hatching to Changes of External Temperature, with four Woodcuts, by Dr. Pembrey, Mr. Gordon, and Mr. Warren. 3. Hæmato-Porphyrin in Normal Urine, by Dr. Archibald Garrod. 4. A Simple Form of Gas Pump, with a Woodcut, by Dr. Leonard Hill. 5. On the Action of Certain Substances on the Hearts of Daphnia, by Mr. J. W. Pickering. 6. On the Comparative Antiseptic Action of the Phenyl-substituted Fatty Acids, by Mr. J.

Parry Laws, F.I.C. 8. On the Effects of the Kneading of Muscles upon the Circulation, Local and General, by Dr. T. Lauder Brunton and Dr. F. W. Tanniciffe. 8. Further Researches on Eye Movements, by Dr. J. S. Risien Russell. 9. Note on the Oxidising Powers of Different Regions of the Spectrum in relation to the Bactericidal Action of Light and Air, by Mr. R. F. D'Arcy and Mr. W. B. Hardy. The part also contains the Proceedings of the Physiological Society at the last two meetings.

The Ophthalmic Review. Edited by Mr. J. B. LAWFORD, Dr. N. M. MACLEHOSE, Dr. K. GROSSMAN, Mr. PRIESTLY SMITH, Dr. JOHN STORY, and Dr. JACKSON. Vol. xiii., No. 157, Nov., 1894. London: Messrs. J. & A. Churchill.—Mr. Ernest Clarke communicates in the present number of this journal a paper on the Association of Blepharitis and Ametropia, with analysis of 100 cases, in which he insists on the importance, in the treatment of these cases, of the use of glasses adapted to correct the errors of refraction that are almost invariably present. Dr. Kenneth Scott, of Cairo, recommends, in a paper on a new method of treatment for vascularised cornea, that each minute vessel should be slit up with the point of a Graefe's cataract knife.

The Quarterly Journal of Microscopical Science. Edited by Professors E. RAY LANKESTER, ADAM SEDGWICK, and W. F. R. WELDON. Vol. xxvii., Part 2, No. 146. London: J. & A. Churchill. 1894.—This part contains five essays, all written by Mr. Richard Ascheton. 1. A Re-investigation into the Early Stages of the Development of the Rabbit, with five plates, containing many figures. 2. On the Phenomenon of the Fusion of the Epiblastic Layers in the Rabbit and in the Frog, with one plate. 3. On the Causes which lead to the Attachment of the Mammalian Embryo to the Walls of the Uterus, with one plate. 4. The Primitive Streak of the Rabbit; the Causes which may determine its Shape, and the Part of the Embryo formed by its Activity, with three plates. 5. On the Growth in Length of the Frog Embryo, with ten plates. The essays reflect much credit on Mr. Ascheton's assiduity. He discusses each subject from a thoroughly independent point of view.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—At a meeting of this society held on Jan. 16th, Dr. J. S. Tew, President, in the chair, Dr. Carroll read a paper on House Sanitation and gave a lantern demonstration. The points dealt with were the following: the site, aspect, and materials used in house building; the necessity for a damp-proof course in house walls and of a layer of concrete under house floors; the sanitary arrangements of dwellings—ventilation, drains, traps, waterclosets, privies, ashpits, cesspools, water-supply, and storage of rain water; the different forms of ventilation, methods of laying house drains, making levels, constructing privies, cesspools, and closets, and sources of pollution of drinking water; effective and defective traps and the necessity of ventilating drains and soil pipes; methods of disconnecting sinks, tanks, and lavatories; pan closets, short hopper and waste-water closets, and the great advantages of the waste-water closet over the ordinary watercloset in cottage property; the right and the wrong way of constructing ashpits and privies; the dangers of pollution of the soil; diarrhoea, enteric fever, and bronchitis; tub closets being condemned as insanitary and expensive, although an improvement on the privy midden. Every dwelling-house should have proper spouting to carry off rain water and prevent it soaking into walls, foundations, and soil; the construction of soft water cisterns and pollution of the water through faulty construction, settlements, &c.; the exclusion of soot, leaves, birds' droppings, &c. by a rain-water separator; the action of different waters on lead and other water-pipes; the construction of wells. There were thirty-nine slides shown of the various defects and remedies in house construction; models of drain-pipes, grease and other traps, short hopper, and slop-water closets were shown. Drs. Tew, Hunter, Watson, Tresidder, and Peshitt spoke, and Dr. Carroll replied. Two specimens of Extra-uterine Fœtation were exhibited by Dr. Watson.

THE LANCET.

LONDON: SATURDAY, JANUARY 26, 1895.

Is the Scripture about to be falsified which says, "Charity never faileth"? All agree in the supreme test of charity—that it is to be found in the sympathy with hospitals. If comfortable men—that is, men of average wealth and health—cannot deny themselves in a sensible degree to help men, women, and children who are both sick and poor there is verily something wrong either with them or with the institutions where such people are accommodated—where a bed is made for them in their sickness and all the resources of modern nursing and medicine are at their disposal. Sir WILLIAM HARCOURT must not be made the sole scapegoat. His Budget may have all the faults attributed to it by its critics; but it will not explain the increasing disproportion between the income of hospitals and their expenditure. We are not going to lose ourselves in the sea of hospital finance in which some swimmers have recently been floundering somewhat curiously. A few facts are patent enough and ought to be noted. Whole wards are closed in some of the oldest, greatest, and best hospitals. In one of the youngest a considerable proportion of the beds has been set apart for pay patients, to the exclusion, of course, of those who cannot pay and for whom this and all other hospitals were primarily built. The newspapers of any given day contain advertisements that are pitiable in their significance. Let us take the *Times* of the day on which we are writing as a specimen. Urgency is the word for the wants of St. Mary's Hospital, University College Hospital, the London Hospital, Queen Charlotte's Hospital, the Royal Free Hospital, the Royal Westminster Ophthalmic Hospital, the Margate Sea Bathing Infirmary, the Metropolitan Hospital, the Royal London Ophthalmic Hospital, St. Peter's Hospital for Stone, the Middlesex Hospital, the London Free Hospital, Guy's Hospital, and St. Thomas's Hospital. In regard to some of these institutions the note of impecuniosity is pitiful. In St. Thomas's Hospital three wards are standing empty, and two others are temporarily devoted to the reception of paying patients. In the Metropolitan Hospital accounts are "overdue" and funds needed for their payment. At the Margate Infirmary 130 beds out of 220 beds are closed for want of funds. At the Middlesex Hospital last year the income from all sources (legacies included) amounted to £20,357 and the expenditure (due to repairs &c.) to £37,184. We need not labour to show that the indebtedness of hospitals is great and unless met by increased liberality of the public likely soon to become intolerable to private persons.

We cannot contemplate the result with pleasure, believing that no hospitals are equal to English hospitals in respect of the humanity and efficiency with which the patients are treated, and being proud of the voluntary and charitable nature of the system by which they have been created and are maintained. The importance of hospitals in respect of

medical education cannot be overstated, and it is insisted on in a letter which we publish to-day. But this is, after all, a secondary function and one which they would still continue to serve even if they came to depend on the State and not on private benevolence. The urgent question is, What are the causes of the declining support of hospitals? We have said that they must be found either in the public itself or in the institutions. We do not believe in any serious decline of charity.

"In faith and hope the world will disagree,
But all mankind's concern is charity."

The age may be luxurious and selfish, or tending towards such undesirable qualities; but we do not believe that this is so to any such extent as to explain the impecuniosity of hospitals. No doubt, too, times have been bad and forms of benevolence other than that represented by hospitals have multiplied, and their promoters are more zealous and importunate than the managers of the hospitals. But the case of the sick poor is so strong and appeals so powerfully to all men that we can only suppose that the failure to meet it depends on some defect in the way in which it is represented or on some error in the selection of fit cases. Our suggestion is that the latter is a principal cause of the decline of hospital support. The promiscuous reception of all sorts and conditions of people, the conversion of wards into hotels for the treatment of those who can pay, the monstrous development of the out-patient department, absorbing half the material that should go to make practice for the men whom the schools educate—these are the evils that chill the ardour of charity. We have long contended that they would operate so, and our contention is being verified. There is charity enough in London and the provinces, we are convinced, to meet the case of those who are overtaken with accident or exceptional disease whose homes have not accommodation for their treatment and whose means are inadequate. But a wide misgiving exists as to the fitness of the recipients—a suspicion that the poor in hospitals are being displaced by those who can pay, and that the resources of hospitals are being frittered away indiscriminately over a great unwieldy mass of people who should have their own medical man as they have their own baker or butcher.

There is one point more painful in this aspect of the hospital problem, and that is that the medical staffs of the various institutions are seriously to blame for allowing such an abuse of the hospitals. We lately referred to the authorities of Guy's Hospital inviting people to come and be treated medically, surgically, and obstetrically for three guineas a week, and advertising a public entertainment for the ventilation of such barefaced competition with medical practitioners. It is no answer to this view that the medical staff is not directly paid in such arrangements. It has the right, and it is under obligation, to protest against them. They cannot be carried out without the consent, if not the assistance, of the staff. In the case of the Great Northern Central Hospital, no doubt, the staff is more to blame for undertaking personally to treat gratuitously the patients of other medical men; but there is something in this bid for large classes of profitable cases made by Guy's Hospital, cases which constitute the very backbone of practice, which is positively startling. These are

not isolated instances. In all hospitals there is an unwarrantable cultivation of the out-patient system and a culpable laxity prevails in the admission of cases that should not be admitted into hospitals for the poor. Our columns testify week by week that the feeling of these evils is becoming intense in the profession. The columns of the newspapers show that it is affecting the flow of subscriptions. In its latter aspect it is a matter for the managers of hospitals to consider very gravely. As regards its bearing on the profession the feeling is ripening fast that something serious will have to be done. It will be unfortunate if the rank and file of the profession are not supported in their protest against these terrible evils by hospital surgeons and physicians. It cannot in the long run be for the interest of consultants to sanction a system which saps at once the very sources of medical practice and the honourable independence of the people.

THOSE members of the newly constituted United Kingdom Police Surgeons' Association who formed the deputation that waited on Mr. ASQUITH on the 17th inst. may be justly congratulated on the success of their labours. They were introduced by Mr. H. NELSON HARDY, who, in a studiously moderate speech, detailed the various grievances which they wished to lay before him. The first was the very inadequate nature of the fees and allowances granted to medical witnesses—a hardship to every medical practitioner in private practice, but specially so to police surgeons, who are, as a rule, gentlemen of experience in the profession as well as in the special duties incidental to their appointment, and whose appearance in the witness-box of all the various criminal courts is necessarily frequent. It is not necessary to give details, as these have so recently appeared in our correspondence columns. It is sufficient to observe that the fee of one guinea per diem does not fairly remunerate even those who live in towns and cities where the assizes and sessions are held, and who, after a long day in court, return home to find some hours of hard work before them before the day's labours are ended. To those living at a distance from the court the hardship is extreme. The remuneration is the same—railway fare, sometimes first-class, sometimes only second, each way, is allowed, and 2s. per night, though this has not always been allowed. One member of the deputation informed Mr. ASQUITH that after deducting all expenses he found himself remunerated to the extent of nine shillings! Other police surgeons less fortunate have found themselves with a balance on the wrong side. A police-surgeon, moreover, may have several cases at the same assizes and on the one day, only receiving the one fee for all. Mr. ASQUITH, while admitting the insufficiency of the fee, observed that other professional witnesses were paid the same; but he was promptly reminded by Mr. T. BOND that the cases were not parallel, medical practitioners having to attend as part of their professional duties, while in the case of a lawyer his appearance in the witness-box was an unfortunate accident. It is a long-established fact that medical practitioners are more frequently called upon as witnesses than members of any other profession. Other members of the deputation, coming from various distant

parts of the country, spoke to the inadequate fees they received as witnesses and the pecuniary sacrifices from which they suffered.

The next point was the very important one of the examination of prisoners accused of criminal assaults on females. For some years past the Metropolitan Police have been furnished by the Home Office with instructions as to how these examinations are to be conducted. The instructions are addressed to the inspector on duty at the stations, and the first is this: "Every prisoner to whom this order applies must be clearly told by the inspector on duty at the station that it is proposed to examine him and that he has the right to object if he so desires, for in the absence of consent any examination would be an assault. The examination is to be made by the divisional surgeon, or in his necessary absence by a duly qualified surgeon. Where consent is given the examination should be made as soon as practicable after the prisoner is in custody and removed to the station and before he is taken before a magistrate." The orders also provide that if a prisoner consents to such examination he is to be told that if he desires the attendance of a qualified medical man on his behalf an opportunity for such attendance with the divisional surgeon will be given, and arrangements are to be made accordingly. Other orders provide for the due recording and verification of the examination and of the compliance with these rules, both by the inspector and by the divisional surgeon. It is obvious that these regulations, which are of the greatest importance, ought to be in the hands of every police surgeon throughout the kingdom. For want of such rules many have been placed in a most difficult position, while some have unwittingly committed the grave error of examining a prisoner without having obtained his consent, both prisoner and surgeon being under the impression that this was not necessary. Even learned judges are not unanimous in their opinions on this point, as was shown to the Home Secretary by one of the deputation (Mr. LOWNDES of Liverpool). Mr. ASQUITH recognised the importance of the request of the deputation that copies of these instructions should be sent to all the police authorities, and said that it would be desirable to issue a circular from the Home Office calling the attention of the various watch and standing committees throughout the country to the existence of those rules.

The third point was this. It had been found by the laborious efforts of Mr. HOPKINS of Bath, one of the honorary secretaries of the association, that there were several large counties and many towns without any regularly appointed police surgeons. Consequently, the nearest surgeon has to be called in, or anyone who may by chance be at hand. Seeing how important and responsible are the duties of police surgeons, it is obviously the duty of each local authority to appoint a surgeon specially qualified for the performance of such duties. The following counties and towns are at present without police surgeons: Anglesea, Carmarthenshire, Denbighshire, Devonshire, Durham, Northumberland, Pembrokeshire, Glamorganshire, Dorking, Echington, Holyhead, Hinckley, Lutterworth, Melton Mowbray, Newcastle-under-Lyme, Pontypridd, Salisbury, Totnes, Whitehaven, Worksop, Glastonbury, Devizes, Haverfordwest, &c.

The fourth point was that in the event of medical certifiers

of the cause of death being appointed, the interests of police surgeons should be safeguarded. In the metropolitan district the divisional surgeon or his deputy is always at hand night and day to attend to any emergency, and it is the practice of the police to call in the aid of the divisional surgeon to any sudden or violent death. A similar practice is observed in many other provincial towns and districts, though the practice is not uniform; but wherever it obtains it is said to work very fairly.

Mr. ASQUITH, in replying to the deputation, said he was glad to have heard their views on points of considerable importance, not only to the medical profession, but to the public. He had already stated what he proposed to do with regard to the very important point of the medical examination of prisoners, and he understood the proposal practically met their views. The main grievance of the deputation appeared to be that affecting the remuneration of witnesses. Now the scale under which medical men and all other professional witnesses were at present paid for attendance at court was fixed so far back as 1858, and in all substantial respects it had remained undisturbed up to the present time. He did not say that this was conclusive evidence of the convenience or justice of the scale, but the facts showed that a number of successive Secretaries of State who had held office had been afraid to burn their fingers by touching it, and he was disposed to imitate their prudent example. Mention had been made that the fee in the Isle of Man was only 15s. 6d. He had made a note of this, and hoped to get it increased to at least a guinea. He agreed with the speakers that the remuneration of a guinea for such duties was altogether inadequate if they looked upon the remuneration paid to witnesses as indemnifying them for the loss in time and money which their attendance at courts of law involved. If it were true that it was a condition of the medical profession to attend courts in a sense which could not be said of other witnesses, then the logical conclusion to his mind was not that this scale of remuneration, which was fixed by the Secretary of State for the whole of the profession, should be altered, but that medical men in their arrangements with their employers—the watch and joint committees—should endeavour to get this circumstance taken into account by these bodies in fixing the remuneration of police surgeons, and they should be asked to make a provision which would supplement the inadequate payment prescribed by the scale. He should be glad to see the police authorities of the country recognise that police surgeons were more liable from the nature of their duties to be called upon as witnesses and to be taken away from the pursuit of their private practice than other professional men. That seemed to him to be the proper way to deal with the subject. With regard to the important point that some counties and boroughs lacked police surgeons altogether, he considered that in the interests of justice and good police administration it was desirable that every police force should have attached to it some recognised accessible and generally known practitioner, not only for the purpose of attending members of the force, but who could be called in to deal with those cases which required special experience. If that course were taken probably the detection of crime would become easier and more effective than it was

at present. He would consider, therefore, whether in the circular to be issued on the other point it was not desirable also to call attention to the desirability of every police force having attached to it some recognised police surgeon with a view to its more efficient administration. Referring to the question of medical certifiers of the cause of death, Mr. ASQUITH intimated that in his judgment, *primæ facie*, police surgeons were the more appropriate and were likely to be more competent persons to discharge that duty than the medical officer of health. It was, however, a matter which did not come within the authority of the Home Office, but he would take care to convey to the Local Government Board, with whom it rested, his opinion that, as a rule, this was the most rational and convenient course that could be adopted.

We fear that the local authorities will hardly appreciate Mr. ASQUITH'S "logical conclusion." His own statement that the scale of remuneration was fixed so far back as 1858, just thirty-seven years ago, is surely ample proof that it is sufficiently ancient to require revising, and if this involves the painful necessity of finger burning on the part of the Home Secretary for the time being, the sooner the painful process is ended the better. Other persons engaged in the administration of justice—learned judges, recorders, clerks of assize, associates, &c.—are reasonably and even liberally remunerated. Why should the economy be all on the side of the witnesses, and especially the medical witnesses? What could have been the intention of offering professional gentlemen 2s. per night, as an allowance presumably for each night's lodging, when absent from home in addition to the one guinea per day and railway fare there and back? If, moreover, a Sunday be included the witness gets no remuneration whatever for this day—an injustice which must occur not infrequently and which has endured quite long enough. Obviously those who summon the medical witness and keep him from his duties and practice for, it may be, some days ought to remunerate him reasonably, and Mr. ASQUITH'S suggestion that the local watch committees should take it into account, though at first plausible, is wholly impracticable; but, on the whole, his reply to the deputation is very satisfactory even on this point, while on the other three points nothing remains to be desired, and we repeat that the members of the deputation may be heartily congratulated. They spoke not only for all duly appointed police surgeons, but for those other members of the profession who perform these duties and are obliged to attend as medical witnesses at a remuneration which we have now official sanction for calling wholly inadequate.

THE question whether, in their selection and purchase of the Stammerham Estate near Horsham as the most appropriate site to which Christ's Hospital should be removed, the Council of this foundation have exercised a wise discretion has been much disputed. It is now some four years since the decision to remove the school from Newgate-street was arrived at in accordance with the scheme of the Charity Commissioners, under which the governors were empowered to dispose of the historic buildings and site that have been one of the most striking features of the City of London.

That the step had become a practical necessity was evidenced by the financial position of the trust, quite as much as by the general considerations of health and sanitation which have led other of the great city schools to be transferred to more open situations. The purchase of the Horsham property was first decided upon, after due consideration and inspection of alternative sites, so long ago as June, 1892. The Council had obtained opinions favourable to its selection from their surveyor and architect; but, having acquired the estate, were impelled by adverse criticism to seek further expert opinions upon the matter. Accordingly, Mr. ROGERS FIELD was commissioned to inquire into the water-supply and drainage of the property, whilst Dr. KELLY was asked to report upon the health of the locality. Their reports, which were received about twelve months ago, have been only lately made public, the Council having in the meanwhile definitely affirmed the acquisition of the site and accepted the plans of the projected buildings sent by the architects, Messrs. ASHE, WEBB, and T. INGRAM BELL. We are fain to confess, after careful perusal of the reports of Mr. ROGERS FIELD and Dr. KELLY, that the site selected is not an ideal one for the erection of a great public school; but we can quite understand that having already acquired it the Council of Christ's Hospital would naturally be loth to reopen the question and seek an alternative site, except on thorough condemnation of the Horsham property by the experts consulted. But neither of these gentlemen do condemn it; indeed, Dr. KELLY considers that the estate possesses advantages in situation and healthiness which render it suitable for the purpose for which it has been acquired. The drawbacks are stated in Mr. ROGERS FIELD'S report, wherein it is shown how they may be overcome. It is clear from his extensive inquiry that the present water-supply is inadequate and liable to contamination; and that to adapt it to the needs of the large school community who will dwell on the estate extensive resort must be had to well-boring. Similarly, as regards drainage and the disposal of sewage he clearly shows—from the analysis of the soil made by Dr. DUPRÉ—that this is mainly strong clay and therefore unsuitable for filtration and irrigation; so that the sewage will have to be subjected to artificial filtration. Moreover, before the land is in a condition suitable for the erection of the buildings it must be thoroughly under-drained. Under these circumstances it seems clear that the site is not an ideal one and also that it is not unlikely that from the health point of view it might have been possible to have found a site which possesses at least as many advantages as those pointed out by Dr. KELLY whilst being free from the drawbacks dwelt on by Mr. ROGERS FIELD. The financial question is another matter, upon which we need not here enter save to remark that Christ's Hospital can ill afford a large outlay for the purpose of remedying the natural defects of the land to which its buildings are to be transferred, and that the scheme is not free from objection on this score. At the same time, if the authorities are mindful of the recommendations that have been made to them, and set about the work in a liberal spirit, there is no sufficient reason—on the side of salubrity—against the estate being adequate for its purpose and the school buildings erected upon it being placed in a good sanitary condition.

That the soil is primarily a clay one does not, on Dr. KELLY'S showing, necessarily mean that it is insalubrious; but in this matter much depends upon the efficiency with which it is drained.

ON Tuesday last the movement for promoting the formation of a Local Teaching University for London passed through one of the most important stages in its career. The creation of a teaching university in and for London is now admitted on all sides, not only to be desirable, but inevitable. The practical question is whether this teaching university should be separate from the present University, or whether the latter should be so reconstituted as to become a local teaching university as well as an Imperial examining board. The proceedings of Tuesday at Downing-street and afterwards at Burlington-gardens will do much to clear up the different views that have been entertained on the question. The scheme of the Royal Commission appointed to consider the Draft Charter for the proposed Gresham University in London was published in THE LANCET of Feb. 10th, 1894, and was absolutely opposed to the formation in London of two universities—one local and teaching; the other Imperial and merely examining—practically being the existing institution. The teaching university was to be grafted on to the examining board, and if the latter suffered it seemed to matter but little, for everyone except the graduates of the University was quite prepared, and some were even anxious, for such a result. A magnificent teaching university, according to the ardent promoters, was to be founded in London, and the "village cobbler," and, may we add, his son (according to Professor SYLVANUS THOMPSON), who is anxious to obtain a degree and improve his position by his force of intellect must stand aside and not spoil such a great conception. Of course, this is a mere idle dream. A federation of colleges, medical schools, and some other institutions will be the only outcome of the report.

There will be no real university in London until the State or the municipality, or both combined, determine to supply the funds that are necessary for such an institution. We should not brook State or municipal supervision or appointment in our British Universities; and without these we can hardly expect any of the public funds to be devoted to the creation or maintenance of a large metropolitan university. Continental comparisons lie quite beyond the discussion. On June 30th, 1894, an attempt was made to force the hands of the Government by asking for a Statutory Commission to be appointed at an early day in order to carry the proposals of the Commissioners into effect. This resolution was passed at a meeting of the delegates from the institutions affected by the scheme, with the exception that the representatives of King's College demurred to the demand for the immediate appointment of a Statutory Commission. The Convocation of the University of London had not then formally expressed any opinion on the scheme. The Government, therefore, not being able to consider the matter as non-contentious, although many of the members were known to view it favourably, took no action last session. During the recess the various bodies concerned have considered the scheme with much fuller consideration, and the result is shown by

the two deputations which waited on Lord ROSEBURY on Tuesday. The first deputation, introduced by Professor HUXLEY, consisting of the representatives of the various institutions affected by the recommendations of the Royal Commission, urged the appointment of a Statutory Commission, but they were all agreed that it should be largely unfettered as to details, that it should be open to hear representations from the various bodies interested, and that, following the lines of the Scottish Universities' Commission, there should be a right of appeal to the Privy Council. The second deputation, consisting of graduates introduced by Mr. FLETCHER MOULTON, Q.C., opposed the union of a teaching university with the existing institution, because it would have a tendency to lower the standard of degrees, damage their impartial character, and injuriously affect provincial and non-collegiate students. Lord ROSEBURY evidently sympathised with the views of the first deputation, and thought but little difficulty was presented by the question of degrees. We think that as the movement progresses more and more difficulty will be found in the adjustment of the standards for the various degrees between the collegiate and non-collegiate students, and we cannot agree for a moment with Sir JULIAN GOLDSMID that these standards will not be lowered. If they are not it is idle to suppose with Dr. ALLCHIN that any much larger proportion of London medical students will obtain the advantages of a London degree than do so at present.

Convocation by a small majority, 203 to 175, passed the resolution moved by Professor S. THOMPSON (p. 244), and by a smaller majority, 157 to 133, a second and consequential resolution. A special committee to prepare a memorandum to lay before the Statutory Commission was then appointed. Although the majority was a small one the fact that the vote in Convocation was in favour of the appointment of a Statutory Commission may determine the Government to take proceedings in the matter in the early part of the session. Lord ROSEBURY says that if a Commission be appointed it will be appointed by statute, which will give every opportunity for discussion in Parliament. Remembering the fate of the Gresham Charter, and the hostility evinced to the present scheme and expressed to the Premier at the graduates' deputation, we should advise our readers not to be too sanguine as to the formation of the local teaching university.

Annotations.

"No quid nimis."

THE NEW DEATH DUTIES.

THE passing of the Finance Act of last year, or, to give it its more familiar name, of Sir William Harcourt's Budget, has made an important change in the position of all persons whose expectations of property are grounded in family settlements or landed estate. The matter is, therefore, one which merits, and is receiving, careful attention at the hands of moneyed people of all classes, and it may be taken for granted that so large an alteration as has been made by it in the incidence of taxation will not take effect without giving rise to many intricate questions and knotty points of law. There will emerge in time and take time for their resolution; but the

main outlines of the new scheme of taxation adopted are clear enough, and it behoves everybody who has the responsibility of making a disposition of property to take effect after his death to consider what its effect will be upon the prospects of those dependent upon him. Broadly speaking, the principle of the measure is to render land and settlements contributory to the revenue in the same manner and to the same extent as personal property. Hence it follows that property in either of these forms, which have hitherto enjoyed a relative immunity from taxation, must stand depreciated in future, and that beneficiaries whose expectations are based upon the devolution of such properties will in future find themselves to some extent disappointed of their hopes. This remark applies, of course, not only to the actual heirs and successors of the present incumbents of the properties, but also to legatees, and to residuary legatees in particular, who are liable to find their benefits cut down by the diminution of an estate in consequence of the operation of the new duties, even when the fresh impost is not directly laid upon the legacy in question. In this way the most carefully adjusted arrangements may be disturbed, and it is precisely those owners of property who have bestowed the greatest care upon their dispositions already made that now need most to reconsider their position, or rather the position of those whom they may expect to leave behind them, in order to satisfy themselves that no injustice can hereafter be done through the action of the new rules as to duty upon the old provisions of the will. There is another way in which the Budget of 1894 affects the estates of deceased persons, and this is of wider application, and even greater importance therefore, than that already glanced at. The new system has not only effected a redistribution of the burdens, but has also increased the total amount of revenue chargeable upon properties of the kind now under consideration. With certain exceptions, which need not be here considered, the new arrangement applies to all estates of upwards of £100, so that few indeed are the numbers, for instance, of our own profession who can be congratulated upon being able to look disinterestedly upon this new departure. From large estates the contribution to revenue will be very large, but even small estates, with scarcely an exception, will not escape scot-free. In some cases we are told on reliable legal authority that very great hardship will be caused to poor legatees by the way in which the rate of duty has now to be assessed. The question is one, therefore, of general interest, and one to which, although it scarcely lies within our sphere to offer advice upon it, we may usefully draw the attention of all our readers. It will be for them to consider for themselves how to act in such cases as those to which we have alluded. In some cases a visit to the lawyer will have to be prescribed; in others some special saving to meet the foreseen emergency. Where a special fund has to be created to bear the burden of the added tax it will in many cases be possible to make provision by means of a small life assurance policy, and we do not doubt that sooner or later the insurance offices, which are alert to anything that has a bearing upon business, will afford facilities for transactions of this kind. But one suggestion certainly cannot be untimely or unsound. The sooner any arrangements of this kind are made the better, for delay in such a matter involves not only the chance of total failure to make the necessary provision, but the certainty that the longer the precautionary measures are deferred the more burdensome they will eventually be.

THE GROCER'S LICENCE.

THE question of the soundness of the policy of granting "off" licences for the sale of alcoholic drinks is one by no means of the least important of the matters which will have

to be dealt with in connexion with that large measure touching the liquor laws to which both Parliament and the Government are committed; but it is hardly a question which can now be disposed of in a separate measure. The difficulty is of course practical rather than theoretical. In the abstract there is no difficulty about isolating this branch of the subject and dealing with it separately in the way either of discussion or of legislation; but in practice the difficulty is so great as to amount to an impossibility. In the first place, the position of the parties to the controversy is such that no advance, however partial, can be made without precipitating a general engagement, and with respect to this particular question of grocers' licences this statement is eminently true. The matter has been treated so essentially as a branch of some more comprehensive scheme of reform of the liquor laws that it would be idle to expect any practical politician to discuss it at the present time as a self-contained proposition. In this sense the discussion which has recently arisen may be called academic; but when the time comes for discussing the whole problem this question of the policy of affording facilities for the purchase of alcoholic liquors, which are so peculiarly liable to abuse, as those which the "off" licence confers, will open up one not only of the most difficult, but one also of the most practically important issues of the whole discussion.

DANGERS IN THE POCKET.

If the reports in several papers last week are to be credited there may exist considerable danger, of which the public should be warned, in the act of carrying in the same pocket certain articles which are in popular request, but which together, as would appear to have been demonstrated, may form a firework ready to "go off" on the slightest provocation. Thus it seems that the simultaneous occurrence of a safety match box and chlorate of potash lozenges in the same pocket led to a series of small explosions, setting fire to the clothes of the unfortunate wearer and severely burning his legs. It is a well-known fact in chemistry, of course, that red phosphorus—one of the constituents of the safety match box rubber—combines with explosive violence with chlorate of potash; but the possibility of such a reaction taking place in a person's pocket has not been foreseen, although, on reflection, we easily see that in these materials there occur two powerful elements—oxygen and phosphorus—which simply yearn, so to speak, to combine. This effected, the lively combustion of the sugar of the lozenge would follow as a logical but very unpleasant sequence. When, therefore, a chlorate of potash lozenge is placed in the same pocket as the safety match box, the pocket is unwittingly converted into a miniature magazine for fireworks, which, if they happen to "go off," cannot certainly be for anybody's "benefit." In any case, a person commits a breach of sanitary law surely when he keeps soothing medicaments in the uncongenial company of a safety match box.

PENNY DINNERS FOR POOR CHILDREN.

SINCE the now classical experiment begun by Sir H. Peek at Rousdon in 1876 the school children's "penny dinner" movement has advanced by strides. The demand for its extension has increased the supply and has also considerably lessened even the small original cost. It will be remembered that as early as 1886 dinners costing a farthing each were provided for the poor children of Birmingham.¹ What is more remarkable, it was found that the nourishment provided at so low a rate was capable of effecting a marked improvement in the physical, mental, and even moral characteristics of the children. It may appear somewhat strange that a difficulty should have arisen at any time in

connexion with the payments, but this is true nevertheless. It is explained by the fact that a large number of poor school children are, so far at least as their teachers know, destitute. To meet their deficiencies more than one plan has been suggested. Some years ago the formation of a Government subsidy for the purpose commended itself to the judgment of certain persons, and the proposal has not yet been entirely abandoned. Hitherto, however, private charity as a rule has come to aid the empty hands of these penniless learners, and accordingly free tickets, given with discrimination to the necessitous, form a part, though not a desired or intended part, of the system. We are pleased to find that this side of the subject has of late been considered with some care. Last week the National Food-supply Association convened a conference of teachers to discuss the feeding of poor children in London schools. The association is founded upon the principle that nothing shall be given away, and so far its efforts have been attended by marked success. It now provides from 14,000 to 15,000 dinners a week, and it has established depôts in the poorest metropolitan districts. Its aim is not merely to provide for want, but also by insisting on the penny, or in some cases halfpenny, payments and by teaching its own simple cookery to show the poor that they can supply themselves with plain, wholesome, and cheap food. Philanthropic persons may purchase tickets for those whom they think deserving, but there are no gratuitous doles. No sensible person will quarrel with such an arrangement. It is not so charitable as to discourage thrift. It does not exclude charity, but it refuses to confound this with business. Its method is thus an eminently rational one and superior in our opinion to any process of merely gratuitous relief. As regards the meals themselves, consisting for the most part of soup and bread, these have met with general acceptance. They are now prepared at one central depôt and issued in insulated vessels. They can thus be kept hot for many hours and supplied at a much less cost than formerly.

DENTISTRY AMONG THE CHINESE.

It would seem that in dentistry as well as in ways that are dark "the heathen Chinese is peculiar," and in the Journal of the British Dental Association for January Mr. C. Robbins has communicated some curious essays on the subject written in English by Chinese students at the Anglo-Chinese College, Foochow. They describe in quaint language the performances of the dentists, who are usually itinerants of the Sequah order. They appear to have three methods of treatment: (1) extraction, the patient's attention being distracted and his lamentations overpowered by the beating of a loud gong; (2) the application of arsenic to kill an exposed pulp; and (3) the extraction of "tooth worms." This latter operation, usually performed by women, is very frequently resorted to, and undoubtedly worms are produced from the tooth, as these amateur dentists adopt the same principle as the lithotomist in the story—who used always to provide for finding his diagnosis had been mistaken by taking a pebble of suitable size in his waistcoat pocket—and themselves introduce these worms, which are usually concealed under their long finger-nails. A Chinese student describes the operation thus; we give his own words: "Now let me advert to the practice of arresting the tooth worms. One of my relatives was once attacked by a severe cold, and after the cold was broken up by restoring activity to his skin he had a neuralgia which gave him such an intense suffering that he could neither eat nor repose, but moaned with a voice so audible and so plaintive that it sent a thrill to the heart of everyone in the house. On the second day his suffering increased to a remarkable degree; indeed, it is impossible even at this distant period to reflect without horror on the miseries of his toothache state.

¹ THE LANCET, Dec. 18th, 1886.

Finally, he submitted to the operation of a woman dentist whose agency was to arrest tooth worms. Her general operation is as follows: a chopstick and a silver pin are the only instruments she requires in her normal act. She is willing to exhibit them to anyone who conceives an inclination of discerning her trickery. She brings the chopstick in contact with the diseased tooth and cautiously pokes it through with a pin in search of the odious worms; after a while scrapes out a lump of yellow minute worms on the chopstick and immerses it in a cup of water. Each lump consists of from ten to fifteen worms, and sometimes two or three hundred worms are scraped if the patient makes an exact bargain at first that the fee should be defrayed according to the number of worms scraped. The general fee is 400 cash (1s. 2d.), and only the poor may take advantage of being in penury to pay 200 cash."

THE MEDICAL SCHOOLS.

SINCE the publication of our table showing in detail the number of students who had entered upon or who were continuing their medical curricula during the session 1894-95,¹ we have received returns from the University of Edinburgh, St. Mungo's College, Glasgow, and Queen's College, Belfast. The new entries at the Edinburgh University show a total of 136, the number of students on the roll, including the fifth year and upwards, being 1213. St. Mungo's College has 21 new entries, with 25 students of the first year, 20 of the second year, 33 of the third year, and 12 of the fourth year. The total number of medical students attending Queen's College, Belfast, is 187, of whom 33 are new entries.

NEED OF NOTIFICATION AT YEOVIL.

THE Yeovil School Board have been in some difficulty owing to the fact that the town council have not adopted the Act relating to the notification of infectious diseases. They observed a falling off in attendances; they knew it was, in part at least, due to infectious sickness, and they sought the advice of the borough medical officer of health as to the significance of the facts and as to the action which they ought to take in them. But Mr. Garland explained that he could not help them. The town council gave him no means of securing accurate information as to the condition of his district as regards disease, or as to the prospects of further spread or of abatement of the current disease. The School Board then did the best they could under the circumstances. They decided to close the infants' school, and then to bring the whole matter under the notice of the town council. It remains to be seen whether the latter body will decide that for the future it is their duty to use the available means for learning what is the true sanitary state of their district, whether suspension of elementary education or other action be in question.

FUNCTIONAL GASTRIC DISORDERS.

IN the *Medical News* of Dec. 15th, 1894, Dr. C. G. Stockton draws attention to gastric disorders dependent upon functional disturbances. We quite agree with him that the question of persistent functional disorders of the stomach is not sufficiently frequently raised. In the treatment of the various forms of indigestion direction is given, as a rule, purely to an attempt to aid the gastric functions to a better performance of their duties, and sufficient attention is not paid to the cause of these disturbances. In the first place, it may be said that the functional gastric disorder is very rarely a primary trouble. In ratio to the ability to hunt down and remove the causal factor will be the success in relieving the neurosis. The stomach, like a mirror, reflects pretty nearly every influence to which the organism is subjected. Irritation of the brain, the spinal cord,

the testicle, the kidney, or the liver results in anorexia, or perhaps vomiting. Grief, joy, worry, and pain lead to similar results. When there is toxæmia from constipation, or renal or cutaneous insufficiency, or other sources, it is the stomach that raises the alarm. In the cerebral anæmia of sea-sickness or of a fainting fit and in the cerebral congestion of sunstroke the gastric are in the tumultuous front of the anarchistic functions. Now, of those suffering from these various irritations—any of which, either through toxæmia or reflex disturbances, may lead to the gastric symptoms—if the stomach contents were examined there would be found no evidence of subacute gastritis, none of the "ropy mucus" which is so much talked and written about, but which those who have largely studied gastric contents usually fail to discover; but there would be found testimony that there had occurred a serious derangement in gastric innervation, exhibiting itself to some extent as excitement, to some extent as depression, and in some instances it is impracticable to say that either of these states predominates. Where will the trouble be found? The nerve irritation may be prone to be some central structural disease or persistent circulatory disturbance, or it may follow excessive mental strain, as seen in actors, school teachers, &c., or it may be, and in fact often is, accounted for by defects in the development of functional disorders. It will also be found that irritation of the spinal cord—either directly, as from pressure in lordosis, scoliosis, and other sources, or interference with innervation, as in tabes and myelitis; or indirectly, as in irritation from hysterical spine—is a common source of gastric disorder. Further than this, the mischief may be lurking in the genito-urinary apparatus. As regards the influence of toxæmia, one of the most common forms results from defects of the kidneys, either dependent upon nephritis or upon renal inadequacy. So alcohol, tobacco, coffee, and other substances may induce digestive disturbance indirectly through the blood and nervous system. Malaria, gout, and tuberculosis often offend in the same manner. Finally, Dr. Stockton lays stress upon the later phases of syphilis being a cause that has apparently passed unnoticed.

THE "NEW STREET DANGER."

THE "new street danger" is losing its novelty. In THE LANCET of Nov. 17th last there appeared comments on the accident connected with electric lighting mains in Cannon-street. Since that time Easton-road and more recently St. James's-street have each been the scene of a similar disaster. Owing to the alarm caused by the frequency and danger of such accidents, it is now proposed to present a petition to the Board of Trade that immediate steps be taken to prevent their recurrence. It is, however, difficult to believe that that Board, aware of the danger and fully informed of the facts, will delay effective action until urged forward under pressure of a public petition. It is not to be doubted—(1) that serious explosions may occur in connexion with electrical leakage in underground mains both on the high-pressure and on the low-pressure systems; (2) that in consequence of leakage from high-pressure mains into the surrounding ground men have been injured and horses killed by electric shock; and (3) that such accidents are to be regarded as "preventable." The causes that lead to them are becoming fairly well known. It is recognised that amongst the measures to avert these occurrences are to be enumerated a due regard to the kind and construction of cables, care and foresight in the laying of mains, a proper "earthing" of the outer conductor of concentric cables, efficient insulation, precautions to secure ventilation and drainage of culverts and junction boxes, and an efficient inspection of the entire system. Such accidents are to be deplored, not only on account of danger to the public, but

¹ THE LANCET, Nov. 3rd, 1894, p. 1061.

also in the interests of electric lighting. The electrical engineer is aware that long before he appeared on the scene with his cables and conduits and junction boxes a notorious gas leakage had long held possession of the ground. It lies with him to meet the difficulty, and he will doubtless prove equal to the occasion. It has been suggested that some gas other than a mixture of coal gas and air—a gas “distilled off the insulating substances” by the heated conductor—may at times be concerned in such explosions. This is possible and in some cases perhaps probable. “The man in the street,” however, is not seriously concerned to know the exact nature of the explosive gas, or the genesis of the spark or arc that ignites it, neither does he claim an opinion as to whether safety is to be found in gastight junction boxes or in a return to the old method of buried mains; but in self-defence he ventures to inquire whether new regulations are needed, whether existing ones are carried out, whether Rule 15, which provides that boxes shall be kept free from water and gas, be a reasonable one, and, if so, has it been duly enforced?

DIPHTHERIA IN LONDON.

DIPHTHERIA showed further decline in its fatal form last week in London, the deaths falling from 35, 50, and 34 in the preceding three weeks to 31 last week, the per case mortality being 20 per cent. The admissions to hospital were 76, some half of the cases newly arising, against 75, 64, and 74 in the preceding three weeks. The patients remaining under treatment last Saturday were 514 in number, as compared with 517 on the Saturday before. Of the 31 deaths, 4 belonged to Chelsea, and 3 each to Fulham, St. Pancras, and Camberwell; and 17 were in children aged from one to five years. In Greater London there were 10 deaths, including 8 in West Ham and district. In 1894 there were notified 18,956 cases in the county of London, this number being at the rate of 45 per 10,000 persons living at the last census. The registered deaths were 3625, and were 1984 above the corrected decennial average. The per case mortality was 19.1 per cent. of notifications.

THE SERUM THERAPEUTICS OF PNEUMONIA.

At the time when the attention of the medical world is directed to the serum therapeutics of diphtheria and tetanus a short review of the same method of treatment as applied to pneumonia, given in *L'Union Médicale* of Dec. 8th, 1894, may prove of interest. Numerous experiments have been made on animals, and several attempts have been made to treat patients in the same manner. Drs. F. and G. Klemperer have treated twelve cases of pneumonia with the serum of rabbits rendered artificially immune. Each dose consisted of from 5 to 10 c.c. injected under the skin of the buttock. Eliminating five of the cases in which crisis resulted as in the ordinary course of the disease, in the remaining seven each time the serum was administered there was a diminution in the height of the temperature and in the frequency of the pulse and respiration, and the patients made a good recovery. They have also injected eight patients with cultures of the pneumococcus which had been heated to 60°C. and so deprived of toxicity. The results were very satisfactory, the temperature falling soon after the injections. They also inoculated patients with the serum of other patients suffering from pneumonia obtained immediately after the crisis. After the inoculations the temperature became lower, and frequently defervescence at once followed. Foa and Carbone reported a case of pneumonia which was arrested on the fourth day after injections of the serum of a vaccinated rabbit. Foa and Scolia injected ten patients suffering from pneumonia with from 5 to 7 c.c. of the serum of rabbits which had been rendered

immune, the injections being given under the skin of the back. In some of the cases as many as three injections were given; in these (four in number) the crisis appeared to be hastened. Jansen also records cases in which this treatment was adopted with success. Lava has treated ten cases of pneumonia with injections of the blood serum products obtained from the viscera of animals suffering from pneumonia. The injections produced no immediate or ulterior local reaction. There was also no immediate influence on the temperature, but the thermometric curve gradually became lower; the frequency of the pulse and respiration was diminished. Convalescence was rapid and no complications followed. Taken as a whole the above series of experiments are satisfactory, and the serum therapeutics of pneumonia deserve further trial and investigation.

“DYSPHEMIA.”

THIS is the name proposed for stammering by Dr. C. F. Coxwell in a recent article in the *Intercolonial Quarterly Journal of Medicine and Surgery*. The article is important as a practical contribution to the elucidation of the cause of this troublesome affection and also its treatment, and is also interesting on account of the theoretical views, which are enunciated. Dr. Coxwell points out that stammering is the result of some interference with the oral or laryngeal mechanism of speech and a consequent want of correspondence between them. He regards it as largely a spasmodic affection, the result of inhibition, which leaves the liberating element temporarily unopposed and so gives rise to spasm. On the other hand, inhibition of the liberating element may cause temporary paralysis. In the next few pages are embodied a description of the relation of the related cerebral centres—speech and auditory—and an account of the gradual development of their functions. He next proceeds to discuss the theoretical question of local control over discharge of energy in nerve centres, and considers the question of the existence of a general inhibitory centre and the nature of neuroses generally. “Dysphemia” is then considered with reference to these theoretical considerations, and an explanation offered of its phenomena. In conclusion, there is a succinct and practical account of the various measures necessary for its successful treatment.

THE CARE OF THE SICK IN WORKHOUSES.

IN spite of repeated practical illustrations the danger of delay where health and illness are in the balance would seem to be still very imperfectly understood either by workhouse officials or by those guardians whose deputies they are. We directed attention to a case bearing upon this subject in our issue of Nov. 24th, 1894. Another example was reported last week. In this instance the sufferer was an aged inmate of Stepney Workhouse. Taken ill on Friday, the 11th inst., he died from syncope on the following Monday. During this interval of three days he received no medical treatment, but was reported by one to another of a succession of employes, till at last within a few hours of his death he saw the assistant of the visiting medical officer. Even then he had to wait another four hours before he could obtain the medicine prescribed. It is curiously suggestive of primitive methods of treatment that the needful remedies in this establishment were “all made up and ready for giving out.” Stock mixtures, we admit, are efficient on occasion, but such absolute faith in their universal suitability argues, to our mind, a dangerous and unwholesome conservatism. Both the coroner and jury who investigated this case agreed in advising that such an institution as this workhouse, which at present contains nearly 800 inmates, ought to be under the supervision of a resident medical officer. Such an arrangement would no doubt prove advantageous in more ways than one. At the same time it

is to be remembered that most of our workhouses have infirmaries attached to them, and that these are usually under the control of two medical men. Thus the wants of workhouse inmates generally are already provided for more or less directly after the manner advised. What, it seems to us, is in the meantime even more urgently needful is the introduction of intelligent energy into the system hitherto employed. It is superfluous to add that any profession of method in arrangement is practically worthless while such neglect is possible as will permit a sick man to suffer unheeded for hours or days, and his treatment, when once begun, to follow the course of a slumberous routine, heedless, apparently, of either symptoms or results. Whether the ideal of actual residence be attained or not, therefore, it is clear that in some parochial unions, at least, the most obvious wants of the sick poor have not yet been provided for.

THE SOCIETY OF PUBLIC ANALYSTS.

THIS comparatively young society, of which the majority of public analysts in this country are members, now occupies a position of unquestionable importance in the public service, in that its aim and work are intimately associated with the supply of pure food and standard drugs. Since its foundation it has evidenced a very healthy activity in all matters pertaining to the Food and Drugs Adulteration Act, and has done most excellent and useful work towards raising the standard of food products, and in publishing through its organ—the *Analyst*—the result of progress in regard to the methods for the more accurate detection of adulteration, which has established it as the standard reference and guide for the analytical practitioner. At the annual meeting of the society, held at Burlington House on Wednesday, Jan. 16th, Sir Charles Cameron referred to the labours of the Parliamentary Committee and to the recommendations drawn up in the form of a Draft Bill by the council, which he hoped the committee would to a large extent be guided by. The society is urging, amongst other important reforms, for a legal provision for the laying down of authoritative standards. On these, as well as other important points, we shall look forward with interest to the evidence which is to be heard from the public analysts before the committee next session. We are glad to see that the society has appointed as president for the ensuing year Dr. Thomas Stevenson, the official analyst at the Home Office, and one of the few analytical representatives of the medical profession.

THE PROPOSED CANTONMENT ACT AMENDMENT BILL.

THE unofficial members of the Indian Medical Congress at their late meeting passed a resolution earnestly representing to the authorities in India and in this country the mischief likely to result from the proposed Cantonment Act Amendment Bill, especially as far as the third clause is concerned, which proposes penal legislation aimed at public medical servants, and implies that they cannot be trusted to loyally carry out the orders of the Government on this subject. From the telegraphic intelligence from India that has since appeared in the public journals of this country it appears that a compromise is likely to be arrived at which will probably involve the abandonment of that clause of the Cantonment Act Amendment Bill when it comes up for discussion. The clause is, in the first place, quite unnecessary, and, in the second place, it conveys a slur on the medical profession. Into the general question of the Contagious Diseases Acts it is needless to enter now. In the present state of political opinion—and until the people of this country realise the vast importance which the prevalence of this class of diseases has upon public health, and the cost and suffering which such diseases entail in the present, and all the

remote consequences by which they are followed—it is not likely that any attempt will be made to deal with the subject by any legislative measures such, for example, as would without hesitation be applied in the case of any dangerous trade or calling. The magnitude of the evil, as far as our army in India is concerned, is undoubted; the facts speak for themselves and need not be exaggerated. There is no room for any difference of opinion in this respect, whatever there may be as to the most efficacious means of dealing with it that may, under the circumstances, be practically open to us to follow in a vast country like India. That something will have to be done in this direction is obvious to most people, and the subject is one for grave consideration. But this clause of the amended Cantonment Act, prohibiting under the penalty of a fine the compulsory examination of any woman by a public servant, is, as we have said, an unnecessary and under the circumstances, as it seems to us, a gratuitously improper proceeding. It is unnecessary because there is already an existing law on the subject, and the Government of India has moreover engaged not to do anything opposed to the resolution of the House of Commons and the orders of the Home Government in the matter. It is improper in that by implication it casts a slur upon the medical profession in India. The medical servants of the Government of that country are not at all more likely to do anything contrary to the laws and regulations of the Government than any other class of its servants. From the nature of their calling, however, they must be more keenly alive to the gravity and extent of the evil than other people can be.

DEATHS UNDER ANÆSTHETICS.

A RECENT death under chloroform which occurred at the Middlesex Hospital exemplifies the grave danger to the patient during that period of chloroformisation called the "struggling stage." The patient, a man of adult age and described as a hard drinker, was to be placed under chloroform in order that one of the surgeons might remove a mass of tuberculous glands in the neck. The man struggled violently during the administration of the chloroform and died suddenly. The heart was dilated and the myocardium fatty. We have no particulars as to the method employed or the phenomena exhibited at the moment when grave symptoms occurred; but it seems likely that, as so often happens, the lethal dose was taken during the deep gasping breaths always present when the patient struggles. There are in such cases two factors at least which tell against the patient—the fixation of the muscles during their spasmodic contraction (the struggling stage), which hinders the output of chloroform by impairing respiratory movements, and by the propulsion of venous blood into the thorax. A very similar case has recently occurred at the Royal Victoria Hospital at Bournemouth. The patient suffered from a fractured patella; he had taken chloroform in November of last year, but except that he struggled in going under he appeared to have done well. On Jan. 4th, however, a second operation being necessary, the man was again chloroformed and again struggled violently. The quantity of chloroform given is stated to have been one drachm, a very small quantity unless given by Junker's inhaler. However, the operation appears to have been commenced and the patient was presumably under the influence of the anæsthetic. Respiration suddenly failed and the circulation quickly ceased before resuscitation could be effected. A death under the A.C.E. mixture occurred recently at the Swansea Hospital. The patient, a young woman twenty years of age, suffering from "housemaid's knee," was anæsthetised by the A.C.E. mixture with a view to "firing" the joint. This was successfully accomplished, and after the anæsthetic had been stopped some three minutes the pulse was observed to grow weak and in a few seconds to stop. The respiration

continued for fully five minutes after this. No loss of colour was seen, although just before the cessation of the pulse the lips became congested. Nothing abnormal about the patient was found before the anæsthetic was given. She was menstruating. This sad occurrence is a very typical one of the usual onset of dangerous symptoms under the A.C.E. mixture. We are not told how it was given in this case; but often it is exhibited from a closed inhaler, regardless of the fact that it contains chloroform and should therefore always be given well diluted with air.

INFLUENCE OF FASTING ON MUSCULAR FORCE.

AN Italian physician, Signor Manea, has recently investigated the influence of fasting for periods of twenty-four and of thirty-six hours on his muscular power, testing this both by voluntary efforts of, and by the application of an electrical current to, the muscles of his forearm. The conclusion at which he has arrived is that fasting within the above limits has no influence on the muscular power. The deviations after longer periods observed by other investigators he thinks are attributable to the effects of the fasting on the nervous system, circulation, and respiration. Signor Manea distinguishes two stages in fasting: one in which a kind of compensation of the injurious effects of fasting is effected through the agency of the nervous system, and a second in which there is deranged compensation, with disturbances of the several organs strongly marked, accompanied by loss of weight and abundant excretion of nitrogen in the urine, after which death occurs. The great powers of resistance possessed by the muscles in regard to their force are, he thinks, due to the glycogen and sugar in the blood, which do not materially alter in quantity even after prolonged abstinence.

THE MEDICAL PROFESSION AND THE STORES SYSTEM.

WE are glad to see indications that our criticisms on this subject in THE LANCET of Aug. 25th last have had some effect. In the price list of June last of one of the Coöperative Societies there were two gentlemen named with whom certain arrangements had been made by the society. We are glad to say that in the December list the number has fallen to one. We must be thankful for a fall of 50 per cent. We shall still treat this matter impersonally in the hope that the solitary member of the profession on this list will soon feel his isolation and the force of our objections. Theoretically it is intelligible how such arrangements should have been hastily consented to; but, on reflection, they will be seen to be objectionable and a clear means of facilitating the taking of the patients of other medical men. The advertisement of names is forbidden by the Stock Exchange, and surely we should not be behind that body in the sense of what is fit. There still remain, we regret to say, the names of four dentists, one of them with a qualification from a medical authority. We appeal to them all to support the principles we advocate—the avoidance of advertising and the refusal to have anything to do with temptations to patients to leave their own medical men, who best know their circumstances and how to adapt charges.

LETHAL AND NON-LETHAL EFFECTS OF STRONG ELECTRICAL CURRENTS.

M. BERNHARDT, in the *Centralblatt für die Medicinischen Wissenschaften*, has collected several instances of death by electricity. In one recorded by Dr. J. Kratter a man aged twenty-six was traversed by a current of high tension—1600 to 2000 volts—and was found breathing stertorously a few steps from the point where he made contact. Death soon took place. The post-mortem examination, after the lapse of twenty-one hours from the time of death, disclosed two

small wounds—one on the left index finger and the other on the back—and there were large extravasations of blood in their vicinity. All the organs of the body showed hyper-venous blood, acute oedema of the lungs was present, and there were extravasations into the sheath common to the carotid and vagus, along all the vertebrae, into the intercostal spaces, around the œsophagus, beneath the peritoneum and elsewhere. The muscles of the body were in an extreme condition of rigor mortis; the heart was partially relaxed. No macroscopic changes could be seen in any part of the nervous system. Kratter thinks that the electrical shock suddenly paralysed the heart, which was the immediate cause of death, accompanied by oedema of the lungs causing hypervenuosity of the blood. There was a marked contusion on the left side of the diaphragm at the point of contact of the heart. Experiments made on animals, showed that in them the respiration was usually primarily arrested, which caused asphyxia and secondary stoppage of the heart's action, though sometimes the heart was first affected. In a second case, reported by M. D'Arsonval, a man was struck with a current of 4500 volts (the ampère meter indicated 750 milliamperes). The current entered at his hand and issued at his back. Half an hour or more elapsed before any attempts at resuscitation were made, but on artificial respiration being practised on Silvester's method recovery took place. Lastly, Dr. Donnellan reports a case of the passage of a current of 1000 volts through a man, which instantly caused coma, dilated pupils, pallor of the face and sweating; delirium, and tonic alternating with clonic spasms followed. The pulse was 80. The respiration, at first stertorous, passed into the Cheyne-Stokes type. After the injection, first of morphia, and then of strychnia the patient fell into a deep sleep, from which he awoke convalescent.

THE HISTORY OF THE ROYAL MICROSCOPICAL SOCIETY.

ON Jan. 16th was held the annual meeting of the Royal Microscopical Society, at which Mr. A. D. Michael, the President, delivered an interesting address on the history of this body. In 1839 a party of seventeen gentlemen assembled at the house of Professor Quekett, 50, Wellclose-square, "to take into consideration the propriety of forming a society for the promotion of microscopical investigation, and for the introduction and improvement of the microscope as a scientific instrument." The outcome of this was a public meeting at the rooms of the Horticultural Society, Richard Owen (afterwards Sir Richard) in the chair, when the Microscopical Society of London was formally started. John Quekett was appointed secretary, an office which he held almost to his death. At his decease certain members of the society subscribed to purchase for the society's collection a curious microscope which Quekett possessed and which had been made by the celebrated Benjamin Martin about 1770, probably for George III., and they extended their subscription so as to provide a medal to be called "the Quekett medal," to be given from time to time to eminent microscopists, and how, difficulties having arisen, it happened that the only Quekett medal ever awarded was given to Sir John Lubbock. The use of the microscope in medicine has become such a routine practice that there is some danger of the younger generations of practitioners forgetting how much they owe to the labours of this society in improving by its influence and assistance an instrument which is now in every student's hands. It is a trite saying that inventions arise according to the need for them, but how much toil and weariness would the older worker have been spared had he possessed the microscope of modern days. With the aid of a frog and a microscope Harvey could have made his immortal discovery in five minutes, and yet perhaps his loss is our gain, for in that case the world would never

have enjoyed his masterly piece of deductive reasoning. Mr. Michael, in considering the future of the microscope, said that he believed there was as much scope for progress in the future as there had been in the past. Perhaps the fantastic ideas of Fitzjames O'Brien will be one day realised, and "from a diamond of 140 carats, submitted to an electro-magnetic bombardment," will be fashioned the perfect lens. Though the modern man of science will probably not see an "Animula" (if he did he would cultivate her in agar-agar), we have little doubt that the improvement of the microscope will still proceed under the ægis of the society, and that with increased powers of definition much that is now necessarily obscure will be revealed.

THE DUKE OF ARGYLL.

THE Duke of Argyll is making very favourable progress. He is regaining his strength steadily, if slowly, the pulse being regular and increasing in force. The fever has now practically left him, as the temperature is usually normal, while an average appetite points to some abatement of the dyspepsia. He has been able to sleep from five to six consecutive hours; and altogether, at the time of going to press, his condition appears to us more favourable than certain disquieting rumours would have led us to expect.

THE SALARY OF THE MEDICAL OFFICER TO THE WIGAN UNION.

THE question of the salary of union medical officers has always been a sore point between members of the profession and the general public, on the one hand, and boards of guardians, on the other. The latter bodies—actuated, no doubt, by a laudable regard for the ratepayer's pocket—have a tendency to behave in a somewhat parsimonious manner towards a hard-working and deserving body of men. At a recent meeting of the Wigan board of guardians a guardian, Mr. J. H. Prescott, drew attention to the fact that the medical officer by means of extras was getting something like £650 a year, and though he had to pay a man £50 out of that it left him with £600 per annum, which he (Mr. Prescott) thought was too much. Extras ought to be abolished and a fixed salary paid, and he considered that the Wigan board ought to apply to the Local Government Board to see if this could not be done. Now let us see what the medical officer does for his £650 per annum, a remuneration which Mr. Prescott finds so disproportionate when compared with the duties. He is absolutely debarred from private practice and devotes his whole time to his public work. The population is 58,000, and Wigan has more out-door paupers than any union in Lancashire. There are 600 permanent order cards, and paupers holding these cards need not trouble the relieving officer for an order, but send in their cards when an order is required. The salary is £130 per annum, with a house, surgery, coals, and gas; £40 are allowed for a dispenser. The extras are midwifery and surgical cases, lunacy and vaccination fees. All these extras come by special order of the relieving officer and are examined by the auditors. The guardians' advertisement stated: "Salary £130. Vaccination fees to Lady Day last £56." These have now, owing to the neglect of the vaccination laws, fallen to £24, but the guardians, we presume, will not make this up to the advertised amount. The extra pay means extra work, and if the relieving officer has given orders with too lavish a hand it is the guardians' duty to inquire into the matter and not stint their medical officer. The principle of a fair day's wage for a fair day's work is an excellent one, and we can imagine no better case for applying it than to that of a union medical officer. Not for him the eight hours day, the Saturday half-holiday, or the weekly rest. At all times he is supposed to be ready to answer any call, to give his time,

his knowledge, and his help to the relief of the poor and suffering, and his reward should be commensurate with his work.

THE DIFFUSION OF SMALL-POX.

IN London there was a death registered last week from small-pox, after the absence of this disease in a fatal form for a fortnight, the death being that of an adult concerning whose vaccination no statement is given. The deceased belonged to Marylebone, in which parish small-pox has lately shown some signs of renewed activity. The fresh cases last week in the metropolis were 10 in number, and the admissions to the institutions of the Asylums Board 6, against 1, 8, and 8 in the preceding three weeks, leaving 32 patients under treatment, an increase from 28 on the previous Saturday. During 1894 the number of notifications of small-pox in the whole of London was 1391, a number equal to 3·3 per 10,000 living in 1891. Among the sanitary areas contributing largely to this total were Marylebone with 417 notifications, Poplar with 124, St. Pancras with 106, Islington with 105, and Bethnal Green with 98, these five districts with less than 25 per cent. of the population contributing upwards of 60 per cent. of the notifications. The registered deaths in the year were 93, as against a corrected decennial average of 312. The per case mortality last year was 6·7 per cent. In the provinces last week the midland towns of the Manor of Aston, Wolverhampton, West Bromwich, and Birmingham had experience of the disease, the three first named lightly and the last named in the form of 2 fatal cases and some dozen or more of fresh attacks. No deaths occurred in Liverpool, but half a dozen cases were heard of there, and also in the adjoining borough of Bootle. In the second week of January matters in Dublin grew worse, the admissions to hospital being 88, as compared with 71 the previous week. The deaths were 11 in number, comprising 5 in vaccinated persons, none of whom were under ten years of age, while of the 6 in unvaccinated individuals 5 were under ten years of age. There were left in hospital 345 patients, including 151 convalescents at Kilmainham.

LORD RANDOLPH CHURCHILL.

IT is not within the scope of THE LANCET to review the political life of Lord Randolph Churchill, or to even attempt to decide concerning his place in and influence upon the history of an empire; we can only in general terms confine ourselves to an expression of deep regret that a man with so brilliant a retrospect, and until two years ago so brilliant a prospect, should have been cut off in mid-career under circumstances of such particular sadness. No one knowing the conditions expressed by the term "general paralysis" could have expected any other than the sad issue to his illness which took place early on Thursday morning last from rapidly increasing congestion of the lungs. All medical readers of the numerous bulletins reporting a most from hour to hour in the daily press the progress of his malady must have seen that the end was coming; and, latterly, despite the lingering course the terrible malady in question is wont to pursue, must have seen that that end was coming quickly. Lord Randolph Churchill's case has throughout been typical of general paralysis. In its history, which we published on Dec. 29th, 1894, it forms a fairly representative picture of the usual symptoms when the disease has well established its hold, while in the story of his life we have many of the elements likely to develop in him latent tendencies towards the malady. High spirited and nervous by constitution, he led an over-full life in every direction. For a considerable time he stood in the van of the Conservative party, and, being distinguished alike by his relentless tactics towards opponents and his irresponsible attitude towards friends, he drained

to the very dregs the heady cup of politics. Official responsibilities were thrust upon him at an early age and at an early stage in his political career, while he continued to double with the life of the statesman—not that of the ordinary statesman, but of the stormy statesman—the life of the great nobleman and the man of pleasure, sport, and fashion. Early success prompted him to over-effort, a great and unexpected check caused him to redouble those efforts, and the result of it all was ruin to his nervous constitution. No political leader of recent times, not even Lord Beaconsfield, has had a more personally affectionate following than Lord Randolph Churchill, and we believe that it will be a solace to his admirers to learn that during the end of his career the hand of sickness was upon him, so that in considering his claims upon their admiration, they must in justice to the sound man neglect the failings of the sick man.

THE spring term of the London Post-graduate Course will commence on Feb. 4th, and will last eight weeks. In addition to courses on General Medicine and Surgery, there will be courses on Diseases of Children, Diseases of the Nervous System, Diseases of the Eye, and Diseases of the Skin, Throat, and Ear, and Bacteriology. The fees are £1 1s. and £2 2s., according to the number of lectures in a course; and we are requested to state that a prospectus can be obtained from the Secretary, Dr. Fletcher Little, 32, Harley-street, W., who particularly desires to hear promptly from gentlemen intending to join the classes.

THE committee which has been appointed by the Clinical Society of London "to investigate the clinical value of the antitoxin treatment of diphtheria" is now definitely fixed upon. It consists of Dr. Church, Dr. Stephen Mackenzie, Dr. Coupland, Dr. Hale White, Dr. Pasteur, Dr. Sidney Martin, Dr. Washbourn, Dr. H. P. Hawkins, and Dr. E. W. Goodall; and we can well believe that the profession will await with interest the joint report of individuals so well fitted to express a practical as well as a scientific opinion. Sir Joseph Lister was invited to join the committee, but was unable to accede to the request of the society.

OWING to pressure on our space we have been compelled to postpone the continuation of our report of the Indian Medical Congress until next week.

DIFFICULTIES UNDER THE INFECTIOUS DISEASE (NOTIFICATION) ACT.

II.¹

2. *Nature of the Visit by the Medical Officer of Health.*

THE medical officer of health having decided that a personal visit by himself is desirable in a given case of infectious disease of which he has become aware, whether under the Act as to notification or otherwise, the question arises as to what should be the nature of that visit. This question has given rise to much difficulty and at times to misunderstanding and even ill-feeling.

In the first place it should be remembered that a medical officer of health has absolutely no right, in virtue of his office or under the Orders relating to his duties, to enter on any private premises. It is true that under Section 102 of the Public Health Act, 1875, it is enacted that the officers of the sanitary authority "shall be admitted into any premises for the purposes of examining as to the existence of any nuisance therein," but the section contemplates the refusal to admit these officers even for the limited purposes specified, and it is only when a magistrate has, after certain formalities,

granted an order of admission that the actual right of entry is acquired in such form that it can be enforced. For this reason it is always desirable that permission to inspect premises should be asked, and, so far as we know, this permission is rarely or never refused when the inspection in question is limited to what is commonly included under the term "premises." When it becomes a question of entering private apartments, and especially sick chambers, then the matter stands on a somewhat different footing. To this point we shall refer later, but for the moment it may be accepted that the ordinary courtesies of life are nearly always quite sufficient to secure inspection of premises on which infectious disease has occurred with a view to "inquire into the causes and circumstances of such outbreak," and of advising "the persons competent to act" as to what may be required "to prevent the extension of the disease," as also of enabling the medical officer of health to "take such measures for the prevention of the disease as he is legally authorised to take."² The contention that it is necessary to extend such visit to the sick chamber has generally been raised in connexion with a visit by the medical officer of health to the sick person concerned; but there have been cases where the two questions have been dissociated, and we, therefore, deal with them apart. On the question as to a visit to and examination of the sick-chamber itself it has been held by the Local Government Board that, whilst the particular circumstances of the special case must decide whether it is necessary to the performance of the duties quoted above from the Order of March 23rd, 1891, that the medical officer of health should have access to a particular room—namely, the sick-chamber,—"in the majority of instances in which cases of infectious disease are notified there is no need for a medical officer of health to personally inspect the apartment for the treatment of the sick person, and that in the remaining instances where such visit may become necessary it should be remembered that, apart from cases to which Section 102 of the Public Health Act, 1875, may be applicable, this can only be done with the consent of those having charge of the patient and that the co-operation of the medical practitioner in charge of the case should be secured if possible." In other words, unless it is believed that there is "nuisance" in the sick chamber and that the cause of the disease is in some way concerned with that chamber, the medical officer of health has no duty under the Order of the Local Government Board and no right under the statute to inspect that chamber.

There are, of course, cases where such inspection may be desirable or even necessary—as, for example, where the chamber of a person suffering from enteric fever is believed to be in direct communication, by means of a sink or overflow pipe, with some drain. Wherever there are such suspicions inspection may properly be requested, such request being best proffered in consultation with the medical attendant, and, if need be, enforced by application to a magistrate under Section 102. This latter action will, however, be but rarely necessary where the ordinary preliminaries are properly observed; in fact, we hardly know of such an instance having occurred.

It will be observed that in regard to visits to the sick-chamber the Local Government Board urge upon the medical officer of health to secure, if possible, the co-operation of the medical practitioner in attendance on the case. This principle may be extended even to the inspection of premises in certain cases, for there will certainly occur in every district cases of infectious disease on premises which should not, according to the current rules of professional etiquette, be visited by another medical man, though a health officer, except after communication with his colleagues. And in this connexion we cannot but recall the fact that in numbers

¹ Part I. was published in THE LANCET of Jan. 19th, 1895.

² See Order, March 23rd, 1891.

of letters which have emanated from the Local Government Board medical officers of health have been urged not to forget "the customs that usually govern the relations of medical practitioners to each other." This, indeed, is the one means by which, above all others, difficulties arising under the Act as to notification can best be avoided.

It has, however, been asked whether a medical officer of health ought not always to assume that, in the sick chamber of a person notified to be suffering from infectious disease, there is something of the nature of a "nuisance" which demands his entry and inspection. Such a view is an extremely strained one. We doubt if any magistrate would, on evidence limited to the existence of a case of infectious illness only, ever grant an order of entry under the Public Health Act; and it is evident that the Local Government Board take the same view. Thus, in a letter written by them, it is stated "that the Board do not regard the existence of every case of notified infectious disease as necessarily involving reasonable cause to suspect the existence of a nuisance on premises such as is contemplated in Section 102 of the Public Health Act, 1875."

But the point that has caused most discussion and trouble has been the practice of some medical officers of health to visit and examine the sick person. Some seem to have done this as a matter of course in the performance of their regular duties and quite apart from any special reason in the individual cases; others, again, have done it by way of satisfying themselves or the authority whom they serve as to the correctness or otherwise of the certificate of notification. Those who have adopted this course as a matter of habitual practice have in certain instances contended that it was their duty so to do. Such was certainly never the intention of the Act relating to notification, and this is the more obvious because no increase of salary to the health officer was made one of the conditions of the adoption of that Act; although it is evident that if the medical officer of health was expected to visit every person notified to be suffering from infectious disease his duties would become very largely increased. And, in answer to appeals made to the Local Government Board on that point that department has again and again announced that "they do not consider that either the Infectious Disease (Notification) Act or any Order of the Board imposed upon a medical officer of health any obligation to visit each case notified to him under the Act"; and they have further reminded authorities that any such examination can only be made "with the consent of the patient or of those having charge of the patient," and that such a practice is not only no duty of the health officer, but that it is, as a rule, "undesirable."

There may, however, be exceptions which may call for departure from the general rule that it is undesirable that the medical officer of health should in virtue of his office make a personal examination of a patient, and two of these exceptions have been recognised by the central authority. Both of them apply to special cases only. The first exception has to do with certificates that are assumed to be fraudulent. In such cases the medical officer of health doubtless has a duty towards his authority, and however much he may regret to perform an unpleasant task it cannot be held that he acts improperly if he protects his authority against that which is believed to involve a breach of good faith on the part of the certifier. The views of the Local Government Board as to this are set out in several letters, one of which we quote in full because it also explains what are the special precautions which should be adopted in visiting a patient with a view to revise the diagnosis that has been made in the notification certificate. The letter, which was addressed on Oct. 1st, 1890, to the town clerk of Bolton, is as follows: "It appears to the Board to be undesirable that the medical officer of health should in general undertake a personal diagnosis of the

notified cases in order to test the accuracy of the certificates. In some cases, as where there is reason to doubt the good faith of the certifier, or where the disease is one which, in itself or owing to the attendant circumstances, threatens exceptional danger to the community, it may be desirable that the medical officer of health should make a personal diagnosis; but it must be remembered that this can only be done with the consent of the patient, or those having charge of the patient, and that the medical practitioner in charge of the case should always be communicated with and his coöperation secured if possible." But want of good faith is not to be assumed merely because the medical officer of health doubts the accuracy of the diagnosis. Quite the contrary, for as the clerk to the Foleshill rural authority was informed by the Local Government Board on March 12th, 1892, "the certifier's statement of the nature of the disease should be accepted unless there is strong reason to believe that he is not acting in good faith."

We have heard of instances in which the medical officer of health has allowed himself to be habitually used by his sanitary authority as a reviser of notification certificates. Such action is naturally resented by his fellow practitioners, and it distinctly lowers the status of the health officer. If it can be more objectionable in one class of official than in another, it is so in the case of medical officers of health who are themselves in general practice, and who thus lay themselves open to the accusation that they are "competitors" for practice. Happily such action is rare, and we trust it will cease altogether.

The Foleshill letter refers to another class of cases—namely, notifications announcing or indicating the existence of diseases which "threaten exceptional danger to the community." Thus a first notification of cholera or of typhus fever in a district where no such disease has for some time past been known to exist may not only justify but may necessitate a personal inspection of the sick person for the purposes of confirming the diagnosis with a view to the adoption of exceptional measures of prevention. In such a case the object of the visit would solely be to enable the medical officer of health to advise his authority as to the needed administrative action, and not for the mere purpose of testing the accuracy of the diagnosis. Under such circumstances the visit should be paid jointly by the medical officer of health and the medical practitioner in attendance, and the ordinary rules followed in consultations should as far as possible be observed. Similar necessity may arise when a group of notifications under an indefinite heading, such as "continued fever," either gives rise to a suspicion of typhus fever or fails to indicate to the medical officer of health what are the measures of prevention which it is his duty to advise or carry out. If by any chance, in these and similar cases, the medical practitioner should, notwithstanding that the ordinary courtesies of professional life have been observed, decline assent to the health officer's visit, then it may well happen that the latter may properly hold that his duty towards the public requires him to secure, if possible, a personal inspection of the sick person. But even then he cannot demand it; the visit can only be paid with the consent of the sick person or of those in charge of that person; and it will be more than ever desirable that the visit should be paid under such conditions as to avoid all possible complaint on the part of the several persons concerned. As a matter of fact, continuous observance of official courtesies in all branches of the duties of the medical officer of health should in themselves suffice to prevent difficulties from arising in such a case as we have described.

Summarising the points thus far adverted to, it may be laid down: 1. That the question of a personal visit by the medical officer of health is a matter to be decided by the medical officer of health, he being the judge as to what

constitutes an "outbreak" for the purposes of the Order relating to his duties. 2. No duty attaches to a medical officer of health to "visit the spot" in every case of notified disease. 3. When he deems it his duty to pay such a visit he should remember that, apart from a magistrate's order, he cannot claim a right of entry to any premises, and that both as regards the occupier and the medical practitioner in attendance their voluntary coöperation should be sought. 4. That the existence of a case of infectious disease in a given apartment cannot be deemed to mean the probable existence of a nuisance in that apartment; and that a medical officer of health should not therefore claim a right of entry on such grounds. 5. That the medical officer of health has no right to inspect patients, that such inspection is as a rule very undesirable, and that it should not be contemplated, even when it is necessary, except after communication with, and if possible in co-operation with, the medical practitioner in attendance on the case.

(To be continued.)

A TEACHING UNIVERSITY FOR LONDON.

ON Tuesday last the Prime Minister received three deputations, who laid before him their views on the Gresham University scheme. One, the first, was composed of the representatives of the bodies within and without the existing University of London not in favour of the adoption of the scheme, and it will be seen that King's College has come into line with the other important educational bodies of London. The other two deputations represented the graduates of London University "desirous of maintaining the Imperial characters of the University," and the Gresham Scheme Amendment Committee. These two deputations were received together as jointly opposing the Gresham scheme, though upon several grounds.

The Deputation in favour of the Scheme.

The deputation included the Right Hon. T. H. Huxley, Professor Rücker, and Sir Henry Roscoe (representing the Professorial Association); Sir John Russell Reynolds, Bart., and Dr. Allchin (representing the Royal College of Physicians of London); Mr. J. Whitaker Hulke (representing the Royal College of Surgeons of England); Sir John Eric Erichsen, Bart., and Sir George Young, Bart. (representing University College); Rev. Prebendary Wace and Sir William Priestley (representing King's College); Sir Julian Goldsmid, Sir William S. Savory, Bart., and Mr. Anstie, Q.C. (representing the Senate of the University of London); Professor Sylvanus Thompson (representing the Committee of Graduates); and Dr. Frederick Taylor (Guy's Hospital), Dr. Sidney Coupland (Middlesex Hospital), Mr. Hutchinson, jun. (London Hospital), Dr. Payne (St. Thomas's Hospital), Mr. Herbert Page (St. Mary's Hospital), Mr. Spencer (Westminster Hospital), Dr. Isambard Owen (St. George's Hospital), Dr. Shore (St. Bartholomew's Hospital), and Mr. Stanley Boyd (Charing-cross Hospital). Representatives of other educational and scientific institutions of the metropolis were also present.

Professor HUXLEY, in introducing the deputation, said that in a matter of this kind the general feeling on educational matters in London would naturally be led by the University of London. The deputation represented the University, its Senate, Convocation, and graduates; in addition, all the principal London colleges, the great medical corporations, the medical schools, and several important provincial institutions were also represented. Finally, an association including practically all those engaged in science (of which he had the honour to be president) was also represented there in his person. He then referred sympathetically to the domestic reasons which had prevented the Vice-Chancellor of the University, Sir James Paget, from introducing the deputation. The ideal of a university, Professor Huxley considered, could not be subject to more divergent views than must the best practical manner of giving reality to any ideal under the circumstances which obtained among the educational institutions of the metropolis, which had grown up, as it were, spontaneously and without plan. This was not the first time that some attempt had been

made to introduce order into what, without disrespect, he thought he might almost term chaos. Sixty years ago the attempt was made, and although what the projectors of that scheme desired was not eventually granted to them they obtained a something, which had undoubtedly proved to have had an immense influence upon the progress of general and professional education and to have done a vast amount of good work. But it was not what the original proposers wanted, which was to have a teaching and learning corporation; that which was eventually established was a purely examining body—the present University of London. The question of the position of educational affairs in London had been under much discussion. Since 1838 two Royal Commissions had occupied themselves with it. They had devoted an immense amount of labour, time, and acumen to the consideration of enormous masses of evidence, and he thought that it would be probably impossible to devise any opinion upon that topic which had not been before the Commissions. The report of the second Commission was admitted to be thoroughly comprehensive, well matured, and weighty, and their principal business there that day was to say that, in principle, they accepted the recommendations of that Commission, and asked that they might be carried into effect with as little delay as possible. At a full meeting of the University of London, held in July last, it was resolved to be desirable to memorialise Government to take immediate steps for the appointment of a Statutory Commission to frame statutes in accordance with the representation of the Gresham Commission, with power to make such modifications as may seem to them expedient after considering any representations made to them by the Senate, Convocation, or any other bodies affected; and that resolution was not only carried in a very full meeting with only two dissentients, but similar resolutions had been passed by the body of delegates referred to in the report of the Commission and by the association of which he had the honour to be president. Whatever modification a particular body might desire, all were of one mind in desiring two things: (1) the formation of a University of London as an organic whole by the voluntary coöperation of the various institutions for learning, teaching, and examining, and (2) the appointment of a statutory authority as the indispensable instrument for effecting the organisation.

Sir JULIAN GOLDSMID briefly supported Professor Huxley and said that under the Gresham scheme the existing standards would not be lowered.

Dr. ALLCHIN said that the Royal College of Physicians in London cordially concurred in the recommendations of the Gresham Commission, and earnestly hoped that a Statutory Commission would be appointed forthwith to give effect to them. At the same time the College fully sympathised with the desire expressed by the various institutions referred to in the scheme, and who had signified approval of it, that the Statutory Commission should be empowered to make such modifications in detail as might appear desirable after hearing the representations of the bodies concerned. The College was impressed with London's need for a teaching university, in which the teachers should have a direct and considerable share in the management, so that the higher instruction might be coördinated and brought into line with the examinations. The Royal Colleges of Physicians of London, and of Surgeons of England, were not primarily educational bodies, and the success of the new University on the lines proposed would bring them disadvantage in pecuniary position and in influence within the medical profession, for at present they examined and qualified the great bulk of the practitioners of England and Wales, while if the new University were constituted a far larger number of medical students would take University degrees, and consequently fewer would take the diplomas of the Conjoint Board. Nevertheless, so impressed were they with the necessity for the new University that they urged his lordship to consider it pressing. In one other respect the College occupied a peculiar position. In view of their long experience and perfection of arrangements for conducting highly technical examinations they claimed to be associated for examination purposes with the new University. The claim had been recognised by the Senate of the London University and by the late Royal Commission. He was instructed further to submit that if the Government consented to the appointment of a Statutory Commission someone thoroughly conversant with the relations of the Colleges to each other, to the medical schools, and to medical education generally should be appointed to the Statutory

Commission. The Colleges and all the medical examining and teaching bodies in London showed with regard to these a remarkable unanimity.

Mr. HULKE agreed with the foregoing speakers, and briefly stated the grounds upon which the Council of the Royal College of Surgeons of England, endorsed by meetings of the Fellows and Members, had concurred in the scheme.

The Reverend Dr. WAGE, while also supporting on behalf of King's College the appointment of a Statutory Commission, drew attention to the fact that in more than one detail the position of that College was compromised.

Dr. FREDERICK TAYLOR said:—"I am here on behalf of ten medical schools in London, and have to express the general concurrence of those schools in the views expressed by previous speakers. They generally approve the proposals contained in the report of the Royal Commission on the Gresham University, and desire the appointment of a Statutory Commission to carry it into effect, but with full powers to make such modifications in details as may seem to them desirable after hearing the wishes of the various institutions concerned. On that Commission it is desirable from the important position the faculty of medicine holds in the present University that one of the members should belong to the medical profession. I should like to point out to your Lordship that the institutions which we represent, commonly known as medical schools, are practically colleges in the faculty of medicine, that they have been affiliated as teaching institutions to the present University of London, and that in fact they very largely serve the purpose of colleges in medicine to the older universities in England, since by far the greater number of the medical students of these older universities pursue their studies for one, two, or three years at the London medical schools before they take their medical degrees. Further, I would point out that, in respect of their systematic teaching, their equipment, the inevitable influence from constant association of the teachers over the students, the length of that association for a period of five or six years, the fact of residence at least in the case of a small proportion of students, these institutions are as valuable for the purposes of education, in its wider sense, as any other colleges forming part of a university. What is wanting to us is this, that with all these qualifications it is nevertheless only a small proportion of our students who attain to a university degree. Unfortunately, the majority, for various reasons, only study for the diplomas which qualify them to practise their profession, which, valuable as tests of medical knowledge, have not the prestige of a university degree. The establishment of a university according to the scheme of the Royal Commission, in which the medical schools were incorporated as constituent colleges, would not only be an inducement for every student to aspire to a university degree, but would also bring the university degree within reach of a much larger number than now attain to it. The student entering upon a profession like that of medicine would then, as he should, look to a university degree as the end of his studies. Further, the association of the schools together in one university would tend in the medical schools as a whole to raise the teaching to a higher standard even than it has at present."

Lord ROSEBERRY, in reply to the deputation, said:—"Professor Huxley and Gentlemen,—I am not in a position to-day to make you a definite announcement of the position of the Government, but I may say this much—that the Government attaches great importance to the report of the Commission presented last year, and is fully sensible that the present time offers a favourable opportunity for the appointment of a Statutory Commission in the sense in which you wish for it. We have here to-day the representatives of various educational associations announcing to us their earnest wish that a question which has caused much controversy and some ill blood should be put an end to speedily, and that in the interests of the metropolis we should not any longer be subject to the reproach that London is without a teaching university. I have agreed to receive the objectors to the Gresham scheme this afternoon, and it would be disrespectful to them to reply definitely to you. It would be to declare myself to have a preconceived opinion. The Convocation of the University of London also meet this afternoon, and no doubt their decision on the matter will be made the subject of Government representation. But I will later, and without loss of time, inform you of the position of Government in regard to the matter. But the proposed Statutory Commission has one condition which has been unanimously laid down, though insisted upon more in some directions than others—that while it should be guided in its principles by the report

of the Commission, it should be to a large extent unfettered in respect to details. Government will, I think, take full heed of that view. But if the Government is able to announce that it will proceed with the legislation required for the appointment of a Statutory Commission it must make a demand in its turn. It will be absolutely necessary, in view of the work of the session, that legislation on this point should not meet with any long or obstinate Parliamentary resistance. I do not know what emollient faculties this deputation may possess with respect to the Parliamentary powers which may be exercised in respect of any proposals we may make; but I would earnestly beseech them to exercise such powers as they may possess if we are finally to be able to announce that we are able to comply with their prayer."

Professor HUXLEY thanked the Prime Minister for receiving the deputation and for his reply. The deputation then withdrew.

The Deputations against the Scheme.

In the afternoon of the same day Lord Rosebery received two deputations introduced by Mr. Fletcher Moulton, Q.C., M.P., which included Dr. W. J. Collins (representing the Gresham Scheme Amendment Committee), Mr. Bompas, Q.C. (representing 900 graduates of London University), Mr. T. B. Napier, LL.D., Dr. Sansom, Mr. Heber Hart, LL.D., and others.

Mr. FLETCHER MOULTON, in introducing the deputations, said that he had been chosen to say a few words because he had not taken an active part in the special efforts which had been made in this matter although he had a close connexion with London University. The scheme for the Gresham University, with respect to which they had met, was broadly described as a proposed union between a teaching university to be formed in London and the old London University. There was no doubt that the scheme had been mainly supported by the school of educationists who considered the chief value of education consisted in the actual teaching derived from teachers, believing that tests by examination merely testified to successful cramming. He felt strongly that those who urged that a teaching university was a good thing forgot that it was unattainable by the bulk of those who had graduated at the London University in years past, the same class as would, he hoped, go through its examinations in the future. In a teaching university it was necessary that the teachers should be the examiners either personally or constituting the board which directed the examinations. Therefore there must be separate examinations for those who resided and those who did not reside; and in the latter case it would be better to leave the work in the hands of those who had already done so well. For if there were only one examination there would be unfairness observed to the two classes of students, or what was of more importance, the reputation for unfairness, for it was impossible to hold for resident students an examination which turned on what they had been specially taught, and with fairness hold the same examination for non-residents. He maintained that the adoption of the Gresham scheme would cripple the University, and that without addition to its teaching efficiency its cosmopolitan character and reputation would be destroyed.

Mr. BOMPAS said that he represented 900 graduates of London University who had expressed their views by mouth and postcard, saying that if a teaching university were required it should be separate from the existing institutions. Most of those whom he represented were in favour of a teaching university in London, but not of the Gresham scheme, which would detract from the position already enjoyed by the holders of the London University degree. There was no pass degree in the world which could compare with that of London. The new institution would be governed by a senate appointed on different principles, and would have for its object local teaching instead of Imperial examination. It would grant degrees for other considerations than examination. In time the examinations would have characters which would make them more suited to the student at London University than to others. It would also cause great delay; for the opponents of the scheme, many of whom were Members of Parliament, would strive to the last against it. London University had no right to object to the establishment of a teaching university in London, but within the last twenty years the Queen had declared that the degrees of London University should not be interfered with without the consent of those who had taken them, and now it was urged that the Queen ought to take advantage of an

Act of Parliament to break that promise. That would not be a right or an honourable course.

LORD ROSEBURY: How many graduates of the University are there?

MR. BOMPAS: Three thousand, seven hundred. He appeared on behalf of the Imperial character of the University against a scheme which was desired by London only.

DR. W. J. COLLINS said that he represented the Gresham Scheme Amendment Committee and objected to the scheme from no narrow vested-interest point of view, but because it would tend to make the influence of the University more local in character. He said, in answer to the Prime Minister, that he could not tell how many graduates were members of the society, but that his views had procured him election to the senate of the University.

MR. HEBER HART, LL.D., considered that a teaching university in London would be essentially local, just as an examining university was Imperial, and he considered that their functions could be kept as distinct as those of the London County Council from those of Imperial Parliament. Of the 3700 members of Convocation at least 1000 did not trouble to give notice of their addresses and so could not be communicated with and might be considered non-effective members altogether, but he knew that the new institution might be popular in London, but it would be intensely unpopular in the country at large.

DR. SANSOM and **MR. NAPIER, LL.D.**, also spoke.

The Earl of ROSEBURY, in his reply, expressed his obligations to the members of the deputations for their consent to merge the two deputations into one for his convenience. He said: "I quite understand that there are two schools of thought before me. First, that school represented by Dr. Collins, whose objections did not seem to be insurmountable. Dr. Collins felt that the standard of examination might be lowered in the University of London by any association with teaching. But it appears to me that he feels that that objection could be met, if in any way he could obtain some guarantee that the standard would not be lowered. There is nothing in the report of the Commissioners which would prevent the Statutory Commission, if it should ever exist, from founding an examination of a separate kind for those students who are not under the teaching of the University. I can conceive the possibility, which seems inconceivable to the members of this deputation as a whole, that there might be some such separate extension framed for external applicants for degrees to the University of London, which should fully maintain, even if the new University did not itself maintain, the standard of examination on which these deputations set such value. This seems to me the common ground on which the two deputations meet. But the second school of thought, represented by Mr. Bompas, goes a good deal further than this. Mr. Bompas has touched on the essential incompatibility between a teaching and an examining university. I find a difficulty in accepting the doctrine that there is such an incompatibility. Mr. Bompas has shown himself much more antagonistic than Dr. Collins, and attentive consideration will be given to his views. You speak of this as a mere London or local matter, but your contention is based largely on Imperial interests. Well, London is the metropolis of the Empire, and nothing in regard to London can be considered local. If we, by obtaining some standard of examination which shall not lower the standard as hitherto known, and which shall at the same time provide a teaching university for London, we shall, I believe, have done the best for London and the Empire; and I am bound to say, what I did not say to the deputation this morning, that our convictions rather point in the direction of the appointment of a Statutory Commission for framing such a scheme which should at the same time be able to receive full representation from you or from any other interests involved enabling them to arrive at a scheme not unsatisfactory both to the London University as it at present exists and to the empire at large. I have spoken to you quite frankly and have no time to say more. What you have said has interested me very much, and I am only sorry if in what I am saying I am not stating what is wholly satisfactory to you."

The deputations then withdrew.

Extraordinary Meeting of the Convocation of London University.

An extraordinary meeting of Convocation of the University of London, adjourned from May 8th, 1894, was held at Burlington-gardens on the 22nd inst. The proceedings

occupied not much less than four hours, and the discussions were occasionally somewhat heated. Mr. E. H. Busk, Chairman of Convocation, presided.

Before proceeding to business Professor Sylvanus Thompson expressed the condolence of the University with the Vice-Chancellor, Sir James Paget, in his recent bereavement.

The report of the annual committee having been adopted, Professor THOMPSON moved a resolution to the effect: "That Convocation is of opinion that there should be one university in London and not two; and that the interests of higher education will be best served by such an enlargement and reconstruction of the existing University as will (while retaining its existing powers and privileges, and without interfering with the efficient discharge of its present duties as an examining body for students from all parts of the British Empire) enable it to promote learning, scholarship, and research as a Teaching University for London." In support of his motion Professor Thompson said that the matter resolved itself into the question whether there should be in London two universities or one. Most of the authorities concerned, including King's College, had now acceded to the recommendations of the Gresham Committee. The true function of a university was to provide means and opportunities of education, and not to restrict itself to the mere testing of the knowledge possessed by candidates seeking its degrees. Professor Thompson alluded to a certain class of candidates for the London degrees as "village cobblers."

DR. ALLCHIN seconded the resolution.

MR. BOMPAS, Q.C., moved the following amendment: "That in the opinion of Convocation it is essential that in any enlargement or reconstruction of the University of London its existing powers and privileges should be retained unimpaired, the efficient discharge of its present duties should not be interfered with, and the high standard of its degrees should be maintained." He considered that the proposals of the Gresham Committee would destroy the high and almost unique character of the London University degree. He considered that the creation of a second university would be preferable to the scheme of reconstruction.

MR. T. B. NAPIER, LL.D., seconded the amendment. **DR. SISLEY** and **MR. FLETCHER MOULTON, Q.C.**, having spoken in support of it, Convocation divided, with the result that 206 voted for Professor Thompson's resolution and 175 for the amendment. There was, therefore, a majority of 31 in favour of the resolution.

Professor THOMPSON then moved the second resolution: "That Convocation, while desiring to express generally its approval of the proposals contained in the report of the Royal Commission, is of opinion that power ought to be given to the Statutory Commission to vary the details of the scheme, and that it ought to be made an instruction to the Commissioners, before framing the statutes and regulations, to confer with duly accredited representatives of the Senate and of Convocation as to the modifications which may be desirable."

MR. COZENS-HARDY, M.P., seconded the resolution.

MR. MOULTON, Q.C., moved an amendment condemning the Gresham scheme, which was seconded by **DR. COLLINS** and lost, the numbers being 157 to 133.

Professor THOMPSON then moved the third resolution: "That a special committee of nine members, including the Chairman of Convocation, be nominated to prepare for presentation to the Statutory Commission, when appointed, a memorandum of points in the scheme of the Royal Commission in which modification is desirable, and with power to confer with such said Statutory Commission and with any committee of the Senate."

MR. NAPIER, LL.D., seconded the resolution, which was agreed to, and the business of the extraordinary meeting was shortly afterwards completed.

AN ALLEGED "OYSTER EPIDEMIC" OF TYPHOID FEVER.

IN a sense it is to be deplored that side by side with the perfecting of etiological methods the delicacies of our daily lives should be coming one by one beneath strong suspicion as being at times vehicles by which disease may be communicated; and, if these suspicions should ripen into certainties, some of our daintiest morsels must needs suffer sterilisation in the cooking pot before they can be consumed in a spirit of equality. That the process

of cooking renders much of our food more palatable is a proposition which few would deny, but it will hardly be contended that such is the case with, for instance, water-cress, salads, or oysters. To submit these articles to boiling water, or even to a temperature sufficient to destroy the Eberth-Gaffky bacillus, is equivalent to depriving them of the characteristics in which resides their charm. Still, if the circumstantial evidence attaching to a recent outbreak of typhoid fever is to be allowed the weight which is apparently its due, either our oysters must undergo a process of sterilisation or a stringent supervision must be exercised over the conditions under which oysters are "fattened" and stored for the market. The outbreak referred to occurred at the Wesleyan College, Middletown, Connecticut, and it has been ably reported upon by Professor W. N. Conn.

These are the facts. Between Oct. 20th and Nov. 8th there occurred among the students of the college in question—where, by the way, there were seven separate fraternities—an outbreak of typhoid fever, the acme of which was reached on Nov. 1st. Suspicion in the first instance fell upon the water-supply, but there was no evidence to show that the water was specifically polluted, and the limitation in the distribution of the disease was incompatible with a thesis of water-carriage. It was also found that the lady students of the college were exempt from attack, and this fact, coupled with others, was held to exclude the drainage as a cause of the disease. The origin and distribution of the milk and the general food-supply were carefully scrutinised, but only to be absolved from blame, and it was not possible to trace the outbreak to personal infection; moreover, on analysing the incidence of the disease upon the students it was discovered that, with but three exceptions, the attacks were solely confined to three out of the seven fraternities; and it was noted that the date of onset in the several cases pointed strongly to some single source of infection common to all the members of the three fraternities, who were attacked, be it observed, to the extent of no less than 25 per cent. of their total number. A possible source of infection such as that referred to occurred in the evening of Oct. 12th, when all the fraternities held their annual initiation supper, and by a process of exclusion it was found that the only articles of diet common to the three fraternities attacked and not to the other four were the raw oysters obtained from a certain oyster dealer.

Of the four fraternities who remained free from attack two consumed no oysters at all, one had cooked oysters, and the other obtained their oysters from a separate dealer. It was found, too, that on a thesis of oyster infection two out of the three exceptions to which reference has already been made vanished; both of them had partaken of the oysters in question. This, however, is not all. There were at the feast certain old students who did not reside in Middletown, as also five Yale College students; and as a result of inquiries which were set on foot it was ascertained that, out of the twenty old students concerning whom replies were received, two cases of typhoid fever had occurred simultaneously with those which had developed at the Wesleyan College, and there were also three attacks of an anomalous illness. Among the five Yale students there developed, four weeks from the date of the supper, two cases of typhoid fever, and although this is a long incubation period it can hardly be held to put the supper out of court—more especially when considered in conjunction with the fact that an exactly similar incubation period was observed in one of the Wesleyan College cases.

Curiously enough, too, there occurred at Amherst College an outbreak of typhoid fever at the same time as that which occurred at Middletown, and it was ascertained that not only was there an initiation supper at Amherst on the evening of Oct. 12th, but that the oysters eaten at the feast were from the same source as those supplied to the Wesleyan College.

The suspected oysters were, it appears, taken from the deep water of Long Island Sound, but before being eaten they were deposited for a day or two in a fresh-water estuary to "fatten." Within 400 feet of the spot where these oysters were placed was the outlet of a private sewer, coming from a house in which were two cases of typhoid fever; and although a physician was only called in on Oct. 11th, and the oysters were removed from the estuary on Oct. 10th, it is to be inferred, as Professor Conn remarks, that the two patients had been suffering from typhoid fever and their excreta had passed into the sewer prior to this date.

Specimens of oysters taken from the freshening grounds were forwarded to Dr. Foote of Yale College, and he was

able to demonstrate that if typhoid bacilli were introduced between the valves of the oysters the bacilli remained alive a sufficient length of time to enable the oysters to be transferred to Middletown and be consumed at the banquet. This outbreak is certainly of very considerable interest and importance; and when one has regard to what apparently is a fact, that the typhoid germs remain for a long time alive in sea water, and to the belief that oysters are now and again deposited near to sewage outfalls, the fact that we only now hear of oyster enteric fever is somewhat surprising. Obviously, however, all the factors necessary to bring about infection through oysters can be but rarely present, and by the exercise of some foresight and supervision it will surely be possible to reduce the risk of oyster-eating to a minimum. In any case the result of the investigation of our own Local Government Board into the subject will be awaited with much interest.

REPORTS OF THE ASSISTANT MEDICAL OFFICERS OF THE LONDON COUNTY COUNCIL.

MANY persons actively though not officially engaged in the work of bettering the houses of the poor expressed no small dissatisfaction when, by the Public Health Act (London), 1891, the conduct of local inquiries was transferred from the Home Office and Local Government Board to the London County Council; and there can be no doubt that the moral effect of, and the public interest excited by, a quasi-judicial inquiry held in open court and fully reported in the local press were most wholesome. But since the appointment of two assistants to the medical officer of the Council, able to devote the requisite time to house-to-house inspection and personal verification of the representations made to the Council, a series of careful reports have been drawn up and printed in the familiar form of those of the inspectors of the Local Government Board, and we may well hope that, whether as records of past shortcomings, indications of improvement, or as affording guidance for future progress, their effect will be more enduring than that of the more obtrusive public inquiries. We have before us the three last issued: Dr. Young's report on Deptford and Dr. Hamer's reports on Whitechapel and on Mile End, the bodies on whose representations these inquiries were held having been the Mansion House Council on the Dwellings of the Poor and the Jewish Board of Guardians. Of these, Mile End appears in the most favourable aspect, though probably not less from natural and social advantages than from any greater activity on the part of the sanitary administration, for in addition to the usual complaints of tardy action, insufficient staff, prevalence of nuisances, overcrowding, &c., we note that in none has there been any attempt to enforce or even to adopt regulations as to houses let in lodgings, one of the greatest powers for good possessed by our local authorities. Dr. Hamer, who deals with the social conditions of the inhabitants of these districts more fully than his colleague, makes considerable use of the statistics of Mr. Charles Booth's work, "The Labour and Life of the People"; he has, moreover, been able to give the death-rates when corrected by the factor for age and sex correction, so much needed in a rapidly growing industrial population.

Dr. Hamer touches upon a point of considerable interest in his discussion of the constitution of the Whitechapel population. He quotes from the Board of Trade report on Immigration, 1894, that "the total number of the class with whom we are specially concerned [foreign immigrants] who arrived in London without through tickets to other countries, less those subsequently sent away by sanitary agencies, was in 1891 something over 7000, in 1892 about 3000, and in 1893 rather below this latter number. These figures, then, setting off the early part of this year against that of 1891, have to be added to those of the census to arrive approximately at the numbers for the present time." On the last census night, Dr. Hamer tells us, Whitechapel housed 13,538 Russians and Russian Poles, as compared with 26,742 in the whole of London, and he then proceeds to show that, on the assumption that the new arrivals for settlement during 1891-3 were distributed to Whitechapel in a like proportion, the census figures relating to the

number of such persons in Whitechapel would require to be increased by upwards of 6000 in order to make them applicable to the early part of the year 1894. This statement gives a fair insight into the conditions with which the sanitary Council's medical officer that, "under these circumstances, the authority have to contend, and establishes the claim of the need for a strong sanitary staff is obvious"; but, he points out, "compared with other districts which more nearly approach to it in the character of the population and the condition of the houses, the sanitary staff of Whitechapel is, notwithstanding the recent increase, numerically weak." It is to be hoped that the Whitechapel district board, who evidently have in Mr. Loane a capable and zealous medical officer of their own, will respond to the invitation to strengthen their staff so that it may be better able to cope with the exceptional conditions of their district.

The recommendations of the Council's medical officer as to Mild-end depend upon the need of an increased staff to deal with houses let in lodgings to which we have referred. The report will doubtless strengthen the hands of Mr. Taylor, the medical officer of health, in providing him with the assistance which will be necessary to enforce the by-laws which the sanitary authority are preparing.

Dr. Young's report on Deptford gives graphic descriptions of dilapidated premises and overcrowding. In this district overcrowding was frequently found, and but little effort had been made to inspect workshops; and, further, the need for better organisation of the staff of sanitary inspectors was pointed out. Fortunately the London County Council are armed with considerable powers in the event of failure of sanitary authorities to comply with the Council's reasonable demands, and in respect to these districts the Council are now possessed of ample information to guide them to a safe and just conclusion. It may be expected, however, that the cogency of the arguments in the reports will suffice to lead to those changes which are recommended.

THE MEDICAL PROFESSION AND FREEMASONRY.

WE have been favoured by Mr. R. F. Gould with a copy of the paper bearing the above title,¹ which he read before the Quatuor Coronati Lodge towards the end of last year. It is a remarkable and rare circumstance to find a layman not only couching his lance in defence of, but actually riding into the arena and casting down his gauntlet as champion and herald of, the claims of the medical profession. It has sometimes been ungraciously and ungratefully suggested that our profession as a profession is a little prone to sound its own trumpet. This we are not concerned either to allow or very strenuously to deny. But assuredly medical men—always in their collective, and often and notably in their individual, capacity—render more useful service to their country than the members of any other profession or body of men whatsoever. Not less assuredly do they, in this country at any rate, fail to receive in recognition of that service those high honours and rewards which are bestowed freely on the eminent divine, the barrister learned in the law, or even the successful trader or persistent (and useful-to-his-party) politician. What nation should not be proud to welcome as a member of its Upper House of Parliament a Lister or a Paget, a Jenner or a Reynolds? When, therefore, we find Mr. Gould coming forward to break a lance on our behalf we feel disposed in very gratitude to give to his achievements a little more of our space than the purely general interest to our readers of the subject of Freemasonry would in itself warrant. And as it is probable that there is hardly a local lodge of Freemasons in the country which does not include "the doctor" among its members, whilst most London lodges have many medical "brothers" on their roll (there is one lodge in London—the "Æsculapius"—membership of which is restricted to medical practitioners),² we are glad to give the publicity of

our columns to his researches. It may be well to say here that Mr. Gould is well known as a Masonic student, and is the author of a standard work on the History of Freemasonry, and that the task he has set himself is to prove that the medical profession has distinguished itself more than any other in the service of Symbolical Masonry. He says: "I must show you, if I can, that it is by the influence of brethren who have been, or are, practitioners in medicine or surgery, more than to the members of any other single profession, that Freemasonry has been shaped and moulded into the form, or perhaps it would be best to say the system (or set of systems), in which we now possess it."

It is rather startling to find (and Mr. Gould gives it with due caution as "tradition") that "Noah was a distinguished writer on medicine, and the possessor of a library, which he bequeathed to his son Shem. Shem was also celebrated for his knowledge of the medical art, and so was King Solomon (Story of the Jews, 270)."

He then deals with the Alchemists, Cabbalists, Hermetical Philosophers, and Rosicrucians, and mentions amongst others Avicenna, Averroes, Maimonides, Paracelsus, Hermes Trismegistus, J. P. van Helmont, Robert Fludd, and Michael Maier. It is to be observed that he states it "is a remarkable fact that the leading alchemists of the Middle Ages, or hermetical philosophers, if not actually physicians (as occurred in the majority of instances), were medical writers of weight and reputation." Dealing with "the moderns" in Part II., Mr. Gould writes, referring to the erection of Grand Lodges, of which the first was that of—

"England, established A.D. 1717. The Duke of Montague accepted the Grand Mastership in 1721, and the society rose at a single bound into notice and esteem. The first of our 'Noble Grand Masters' was a Fellow of the Royal College of Physicians (as was also the fourth of the series, the Duke of Richmond). The first Deputy Grand Master was Dr. John Beale, 1721; and the first Initiate—after a Masonic torpor of some duration—was Dr. William Stukeley, whose admission took place in the same year."

It is interesting to note that in the foundation of the three great Masonic charities members of the medical (if we include the dental) profession were intimately concerned—Chevalier Bartholomew Ruspini with that of the Royal Masonic Institution for Girls, Surgeon F. C. (afterwards Sir F. C.) Daniel with that of the Royal Masonic Institution for Boys, and Dr. R. T. Crucefix with that of the Royal Masonic Benevolent Institution. Amongst office-bearers of the Grand Lodge of England since 1813 we note the following names:—John Havers (described as "the greatest Masonic statesman of the century"), Thomas Joseph Pettigrew, three past Presidents of the Royal College of Surgeons of England—viz., Henry Hancock, J. Cooper Forster, and Sir Erasmus Wilson,—Alfred Meadows, and W. Rhys Williams, as well as several members of the profession who are happily still alive.

We need offer no excuse for reproducing the following interesting reference to—

"Edward Jenner, the discoverer of vaccination, who was born at Berkeley, Gloucestershire, in 1749, after studying in London under John Hunter, settled at his native place as a medical practitioner. In the Grand Lodge Register, London book, there appears at the No. 449, and under the year 1792, *Country Stewards Lodge* (constituted July 25, 1793). The last entry is dated 1793, and a memo states—'Removed to Berkeley, Gloucester.' In the *Country book*, and at the same number, 449, will be found, '*Lodge of Faith and Friendship, Berkely, Gloc.*' also the words—'Removed from London.' Among the entries are,

"4. Nov. 1802, Wm. Fitzharding Berkeley, Esq. Viscount Dursley, age 17, Berkly Castle, and
"30 Dec. 1802, Ed. Jenner, M.D., Berkly."

"It would seem probable that Dr. Jenner had been initiated in earlier life, and became one of the first joining members of what was virtually a new Lodge established at the place of his abode?"

Then follows a long but necessarily very incomplete list of living medical Masons. Under Scotland we need only allude to the names of Sir William Fergusson and Sir James Young Simpson. In Ireland we note that many distinguished living members of the profession are Masons. Mr. Gould deals at some length with foreign countries, but space forbids our doing more than recording that it was of an American physician and Mason, Dr. Winslow Lewis, that Oliver Wendell Holmes wrote:—

"You hear that man laugh? You think he's all fun,
But the angels laugh too at the good he has done;
The children laugh loud as they troop at his call,
And the poor man that knows him laughs loudest of all."

In the discussion which followed the reading of the paper the rival claims of the profession of divinity and the army were advanced, but Mr. Gould stuck firmly to his text that "the first place of all, from among the professions, in the

¹ Margate: Printed at "Kehle's Gazette" Office. 1894. [Reprinted from "Ars Quatuor Coronatorum."]

² Curiously enough, a letter from Dr. Dutton, the Secretary of the Æsculapius Lodge, is published in our present issue, which likewise contains an appeal from a distinguished medical Mason, Dr. F. E. Clarke, on behalf of the masonic memorial which is being raised to the late Surgeon-Major Parke.

history and expansion of *Symbolical Masonry*, I submit, must be freely conceded to our medical brethren." We have little criticism to make, but must express our regret that Mr. Gould has made any endeavour to estimate the *professional* work of still living medical men—a task which is quite beyond the province of any layman. The result is sometimes almost comical—for example, a distinguished physician of the London Hospital is set down as "Examiner in Medicine, R.C.S.," *et praterea nihil*. We notice also one or two trivial inaccuracies—such as that a certain brother belongs to a lodge of which we happen to know that he was never a member and the misspelling of Mr. Cooper Forster's name. It would be strange, however, in a work which must have involved such enormous labour and research if a few slight errors had not occurred. On behalf of the medical profession we tender thanks to the author for the pains he has taken to support their claims in connexion with Freemasonry.

SMALL-POX IN OLDHAM IN 1893.

THE last report by Dr. Niven in his capacity of medical officer of health for the borough of Oldham has just been issued, and though late in appearing, having reference to 1893, it is not without present interest. The section wherein the epidemic of small-pox is treated in its relationships with vaccination and with the Westhulme Small-pox Hospital is especially of interest just now. The cases of that disease treated in the hospital during 1893 were 638 in number, and of these 403 came from the several wards of the borough, and other 167 and 41 respectively from the adjacent local board districts of Chadderton and Royton. The borough cases yield an attack rate of nearly 30 per 10,000 of estimated population, and the 41 deaths a mortality rate of 3 per 10,000 living. The epidemic was a continuance of the prevalence of 1892, during which year 75 cases came to the knowledge of the medical officer of health. The prevalence of 1892 could be assigned to three causes—namely, the potency for harm of the Westhulme Hospital, the prejudice existing against vaccination, and the non-recognition of mild cases of the disease.

In regard to vaccination the hospital data for 1893 are very striking, as the following statement shows. Among the 638 cases there were 64 deaths, a mortality rate of 10 per cent. of attacks; but this rate was made up of 3·6 among the 472 vaccinated patients, of whom 17 died; and of 27·6 among the 156 unvaccinated patients, of whom 43 died. Of 10 cases "doubtful" as to vaccination 4 proved fatal. Stated in age periods the figures run thus:—

Hospital Cases.

At ages—	Admitted.		Died.		Mortality per cent. of attacks.	
	Vacci- nated.	Not vacci- nated.	Vacci- nated.	Not vacci- nated.	Vacci- nated.	Not vacci- nated.
0 to 5	14	56	1	18	7·1	32·1
5 to 15	35	115	0	9	0·0	15·3
15 to 25	152	16	3	5	2·0	31·2
25 to 35	155	21	4	7	2·6	33·3
35 to 45	79	3	5	3	6·3	100·0
45 and upwards.	37	1	4	1	10·8	100·0
Totals at all ages	472	156	17	43	3·6	27·6

Dr. Niven well says that the figures are unmistakable in their significance. Without the differentiation of the vaccinated class among primary and revaccinations, which is wanting in the report, we see small-pox among the unvaccinated as compared with the vaccinated nearly eight times as fatal at all ages and nearly twelve times as fatal in the first fifteen years of life. The remaining data speak for themselves.

As regards hospital influence, Dr. Niven, proceeding on the same lines as in 1892, has arrived at the following figures, which represent the number of cases of small-pox in each 100 houses around the Westhulme Small-pox Hospital: quarter-mile zone round hospital, 12·9; between quarter and half-

mile zone, 6·6; half-mile and three-quarter mile zone, 2·0; three-quarter and one mile zone, 1·5; outside the mile radius, 0·8. The steadily diminishing incidence of small-pox is well marked as the distance from the hospital increases. If the outside radius attack rate be taken as unity, the several quarter-mile radii become 1·9, 2·5, 8·2, and 16·1 as we approach the institution. The effect thus attributed to the hospital is not to be looked upon merely as a continuance of the heavy incidence arising out of the 1892 prevalence and to be accounted for by the spread of the disease by personal infection or the like, since, among other things, there has been much more vaccination practised in the vicinity of the hospital than in other parts of the town; whilst on the removal of acute cases outside the town towards the close of 1893 attacks ceased to occur near the hospital, and the disease speedily died out entirely. We can add the testimony of Oldham in 1893 to the evidence now so largely accumulating to show the potency for harm of small-pox hospitals upon adjacent populations. The need for vaccination and revaccination of such—and, indeed, all—populations is no less evident.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Dr. H. T. Bulstrode's Report on the Sanitary Condition of the Village of Linslade, and on Diphtheria there.—The village of Linslade, which had in 1891 a population of 1982, is described as within the Leighton Buzzard rural district, contiguous to the town of that name, and as really urban in character. But though urban in type it lacks all the requirements of an urban district. The water-supply is from local wells, which, though of some depth, are dry-stained, and are placed in such relation to privies and other sources of filth that, according to Mr. Sandell, the medical officer of health, three-fifths of them are polluted. And Dr. Bulstrode takes occasion to say that Mr. Sandell is an energetic and an accurate officer. The sewerage of Linslade involves the humorous fact that, though glazed pipe sewers of nine-inch and fifteen-inch glazed ware were laid some thirty years ago, no one could find them, and Dr. Bulstrode, having sought some external evidence of their situation, can only say that in so far as the ordinary visible means of ventilation, inspection, and flushing are concerned these do not exist. But the two streams in Linslade are exceptionally foul, and they are admitted to have been the cause of well-nigh endless complaints because they have been turned into open sewers. Of closet arrangements the only good thing that can be said is that in those cases where pall-closets are resorted to, and these are replacing the vault privies, a scavenger does the cleansing, and removes the contents. In 1894 there were thirty-three cases of diphtheria in twenty-four houses in Linslade, and school operations served largely to extend the disease, school closure being freely resorted to in order to control its diffusion. The description given by Dr. Bulstrode as to Linslade and the surroundings of the houses is by no means complimentary to the sanitary authority and their administration of the place; and he tells the local sanitary authority, through his official report, that "it is difficult to see how, in view of his multitudinous duties," the inspector of nuisances, competent as he may be, "is able to devote proper attention to the Leighton Buzzard rural sanitary district."

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Lancaster County Sanitary District.—Some idea of the urban character of the county may be gathered from the fact that Mr. Edward Sergeant, the county medical officer of health, has received reports from district medical officers of health representing 112 urban and 23 rural districts. Two local authorities have failed to furnish reports to the County Council, and Mr. Sergeant suggests that the Local Government Board should be communicated with on the subject. We are sorry to hear from Mr. Sergeant that "there is evidence of an increasing tendency on the part of medical officers of health to modify the vital statistics of their districts by the undue exclusion of deaths." It appears that a very considerable number of deaths which took place in the county have

not been accounted for in the reports of medical officers of health. Mr. Sergeant has done well to call attention to this omission. The infantile mortality in many parts of the county was exceptionally high during 1893, more especially in some of the colliery districts; Mr. Sergeant remarks that the latter fact suggests that the conditions incidental to the late coal strike may have had some influence either directly or indirectly in bringing about the increased infantile mortality, and this opinion seems to be shared by several of the district medical officers of health. Mr. Sergeant thinks that section 17 of the Factory and Workshop Act (1891), which prohibits the employment of women within four weeks of childbirth, should have a very salutary effect, but he adds that so far no information has come beneath his notice as to the working of this section. In relating the history of small-pox in the county Mr. Sergeant refers to the fact that in the districts of Chadderton and Failsworth the introduction of small-pox was attributed to infection conveyed from the Westhulme Hospital belonging to the corporation of Oldham. Dr. Patterson of Chadderton states in his annual report that during the two months in which the Westhulme Hospital remained free from acute small-pox not a single case occurred in Chadderton. Mr. Sergeant quotes figures from the report of the Local Government Board (1892-93), showing how the Vaccination Acts are carried out in the several districts in Lancashire. The proportion of children not finally accounted for as regards vaccination varies from 74.4 per cent. in the Oldham Union to only 1.8 per cent. in the Bolton Union. In connexion with phthisis Mr. Sergeant remarks that, although the notification of the disease may be theoretically desirable, there are several practical objections to the way of carrying it into effect, and he points out that for the present the efforts of sanitary authorities can be properly directed to the amelioration of those conditions tending to favour the development of the disease. Eighty-four per cent. of the population of the county is, Mr. Sergeant states, protected by the provision of compulsory notification. Prestwich during 1893 added measles to its list of notifiable diseases, but Clayton-le-Moors relinquished it "from a financial point of view." In referring to the Isolation Hospitals Act, 1893, Mr. Sergeant remarks that "the necessity of separate hospitals specially isolated for the treatment of small-pox emphasises the importance of combination." The Housing of the Working Classes Act, 1890, does not seem to be carried out with much energy in Lancashire, and Mr. Sergeant tells us that comparatively few inspections are reported to have been made under the Act. Dairies, cowsheds, and milkshops do not, it appears, receive sufficient supervision in this county, and in some districts they are entirely ignored. Dwellers in manufacturing districts will read with pleasure the following extract from the report before us: "Private enterprise at Chadderton and Middleton has proved successful in reducing the smoke nuisance in those districts, and the fact has been effectually demonstrated that with boiler furnaces properly constructed the complete abolition of smoke is quite possible." A summary of the several district reports is given by Mr. Sergeant, and at the close of his report are full statistical tables.

Sheffield Urban Sanitary District.—The corrected death-rate of Sheffield during 1893 was 24.01 per 1000, a slight increase on the preceding year. The fluctuations in the infantile mortality for the last six years are shown below:—

Year.	Per 1000 births.	Year.	Per 1000 births.
1888	179	1891	170
1889	170	1892	167
1890	195	1893	193

After carefully studying the distribution of enteric fever in Sheffield Dr. Harvey Littlejohn reports that there is a comparative freedom from the disease in those parts where waterclosets are in use, whereas in those portions of his district where midden privies are in vogue there is frequent recurrence of the disease, more especially in yards and houses using a midden privy in common; in fact, Dr. Littlejohn tells us that he hopes to be able to show at a future date that enteric fever has often reappeared year after year in the yards and localities where the midden has once received the discharge of an infected person. Dr. Littlejohn refers to the great difficulty of ensuring proper disinfection of excreta in the houses of the ignorant poor and to the impossibility of efficiently disinfecting a capacious midden privy. He also lays stress on the desirability of hospital isolation in typhoid

fever. Six deaths were registered in Sheffield as due to plumbism during 1893, but five out of the six were brought in contact with the metal in their employment, and the sixth acquired the disease five years ago, apparently from the water as then supplied to Sheffield. The notification of erysipelas is, Dr. Littlejohn considers, of doubtful value, and he has not met with any instances where the disease spread from the infected person to members of the same family. It has been resolved to erect a separate small-pox hospital for thirty-two beds, but apparently further isolation accommodation will be required before long. It is very gratifying to learn that since higher salaries have been given to sanitary inspectors and more experienced men obtained the routine work in dealing with the abatement of nuisances has been carried on with less friction. In the matter of smoke prevention steady improvement appears to be taking place from year to year, and the following figures show the average number of minutes per hour during which black smoke has been observed since 1889:—

Year.	Minutes.	Year.	Minutes.
1889	11.0	1892	5.2
1890	7.0	1893	2.8
1891	6.3		

Under Part II. of the Housing of the Working Classes Act, 1890, thirty-six houses were condemned during 1893 as unfit for human habitation, and under Part I. Dr. Littlejohn received an official representation from twelve ratepayers as to a crowded and insanitary area in the centre of the town. He was able to demonstrate that the mortality-rate in the area referred to was much in excess of those in the borough as a whole, and an improvement scheme has been prepared for dealing with the area in question.

Glamorgan County Sanitary District.—Only a small proportion of the district reports in this county are printed, and there is, we regret to say, little or no improvement in this direction since 1892. It is somewhat a serious reflection upon the local authorities that they do not evince sufficient interest in the sanitary affairs of their district to wish even to peruse the reports of their medical officers of health. Dr. W. Williams, the county medical officer of health, remarks that there is a want of uniformity in certain reports as to the calculation of zymotic death-rates, some medical officers of health including influenza and erysipelas, others excluding diarrhoea. It appears, too, that in some districts proper allowances are not made for deaths in public institutions in calculating the vital statistics. Weekly returns of notifiable infectious diseases are made to Dr. Williams and the complete list is issued by him to all the district medical officers of health. Since Dr. Williams's appointment he has made a sanitary survey of the whole administrative area, so that he is well informed as to the general sanitary condition of the county. The general death-rate for the urban districts was during 1893 19.2 and for the rural districts 19.1 per 1000. There was, however, considerable discrepancy between the urban and rural districts in the matter of infantile mortality, the rate for the former being 168.4 per 1000 births, as against 135 for the latter. Dr. Williams urges upon the Glamorgan County Council the desirability of following the examples of such county councils as have established lectures for sanitary inspectors in their respective counties. Diphtheria and croup are, it seems, but little known in Glamorgan and are confined to certain districts. Puerperal fever caused 67 deaths in this county during 1893, the case mortality being 72.8 per cent., and Mr. Dyke, one of the district medical officers of health, very properly calls attention to the danger caused by midwives laying out the bodies of dead persons while they are attending to their usual duties. Dr. Williams has recently presented to the county council a report embodying returns from several of the local authorities as to isolation accommodation and the action taken under the Housing of the Working Classes and the Rivers Pollution Prevention Acts. The returns in several instances are far from satisfactory. In the return as to the Housing of the Working Classes Act we see that in some places the Act has not been "adopted."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6809 births and 4407 deaths were registered during the week ending Jan. 19th. The annual rate of mortality in these towns, which had increased in the preceding three weeks from 18.0

to 20.1 per 1000, further rose last week to 21.7. In London the rate was 20.0 per 1000, while it averaged 22.9 in the thirty-two provincial towns. The lowest rates in these towns were 12.9 in Plymouth, 14.4 in Cardiff, 15.1 in Leicester, 17.9 in Nottingham, and 18.9 in Birkenhead; the highest rates were 27.9 in Birmingham, 28.3 in Liverpool, 29.3 in Bolton, 30.7 in Sunderland, and 33.4 in Wolverhampton. The 4407 deaths included 338 which were referred to the principal zymotic diseases, against 399 and 363 in the preceding two weeks; of these, 96 resulted from measles, 66 from whooping-cough, 63 from diphtheria, 49 from diarrhoea, 36 from "fever" (principally enteric), 25 from scarlet fever, and 3 from small-pox. No fatal case of any of these diseases occurred last week in Halifax; in the other towns they caused the lowest death-rates in Nottingham, Cardiff, Bristol, and Sheffield, and the highest rates in Croydon, Sunderland, Newcastle-upon-Tyne, Salford, and Gateshead. The greatest mortality from measles occurred in Plymouth, Newcastle-upon-Tyne, Leeds, Portsmouth, and Gateshead; and from whooping-cough in Newcastle-upon-Tyne, Blackburn, and Preston. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 63 deaths from diphtheria included 31 in London, 6 in Birmingham, 4 in West Ham, and 3 in Liverpool. Two fatal cases of small-pox were registered in Birmingham, and 1 in London, but not one in any other of the thirty-three large towns. There were 33 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 19th inst., against 16, 23, and 28 at the end of the preceding three weeks; 6 new cases were admitted during the week, against 8 in the preceding two weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1653, against 1890, 1779, and 1713 on the preceding three Saturdays; 154 new cases were admitted during the week, against 116, 128, and 130 in the preceding three weeks. The deaths referred to diseases of the respiratory organs in London, which had been 319 and 389 in the preceding two weeks, further rose last week to 399, but were as many as 362 below the corrected average. The causes of 82, or 1.9 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Cardiff, Bolton, Newcastle-upon-Tyne, and in six other smaller towns; the largest proportions of uncertified deaths were recorded in West Ham, Salford, Burnley, Blackburn, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21.8 and 25.5 per 1000 in the preceding two weeks, further rose to 28.3 during the week ending Jan. 19th, and exceeded by 6.6 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13.7 in Perth and 21.0 in Aberdeen to 31.0 in Glasgow and 31.8 in Greenock. The 817 deaths in these towns included 45 which were referred to measles, 19 to whooping-cough, 12 to diarrhoea, 9 to diphtheria, 7 to scarlet fever, 5 to "fever," and 3 to small-pox. In all, 100 deaths resulted from these principal zymotic diseases, against 81 and 113 in the preceding two weeks. These 100 deaths were equal to an annual rate of 3.5 per 1000, which exceeded by 1.8 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 38 and 58 in the preceding two weeks, declined to 45 last week, of which 24 occurred in Glasgow, 13 in Edinburgh, and 6 in Aberdeen. The 19 deaths referred to whooping-cough corresponded with the number in the preceding week, and included 13 in Glasgow and 3 in Greenock. The fatal cases of diphtheria, which had been 4, 11, and 14 in the preceding three weeks, declined again to 9 last week, of which 3 occurred in Edinburgh and 3 in Leith. The deaths from scarlet fever, which had been 8 and 6 in the preceding two weeks, were 7 last week, and included 2 in Glasgow and 2 in Aberdeen. Of the 5 deaths referred to different forms of "fever," 3 occurred in Glasgow; and of the 3 fatal cases of small-pox 2 were registered in Edinburgh and 1 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 154 and 215 in the preceding two weeks, further rose to 235 last week, and exceeded by 85

the number in the corresponding period of last year. The causes of 62, or nearly 8 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased from 25.4 to 31.0 per 1000 in the preceding three weeks, further rose to 40.9 during the week ending Jan. 19th, a higher rate than in any week since January, 1894. During the past three weeks of the current quarter the death-rate in the city has averaged 33.4 per 1000, against 18.9 in London and 24.5 in Edinburgh. The 274 deaths registered in Dublin during the week under notice showed an increase of 66 upon the number in the previous week, and included 23 which were referred to the principal zymotic diseases, against 10 and 19 in the preceding two weeks; of these, 10 resulted from small-pox, 4 from whooping-cough, 4 from "fever," 4 from diarrhoea, 1 from scarlet fever, and not one either from measles or diphtheria. These 23 deaths were equal to an annual rate of 3.4 per 1000, the zymotic death-rate during the same period being 1.7 in London and 4.9 in Edinburgh. The fatal cases of small-pox, which had been 5 and 11 in the preceding two weeks, were 10 last week. The deaths referred to different forms of "fever," which had been 2 and 3 in the preceding two weeks, further rose to 4 last week. The 4 fatal cases of whooping-cough also showed a further increase upon those recorded in recent weeks. The 274 deaths registered in Dublin last week included 41 of infants under one year of age and 80 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons considerably exceeded those recorded in any recent week. Five inquest cases and 6 deaths from violence were registered; and 102, or more than a third, of the deaths occurred in public institutions. The causes of 27, or nearly 10 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING 1894.

COMPLETE statistics relating to sickness and mortality during the year 1894 in each of the forty-three sanitary districts of London are summarised in the accompanying table. The mortality statistics relate to the deaths of persons actually belonging to the various sanitary districts, and are the result of a complete system of distribution of deaths occurring in the institutions of London among the various sanitary districts in which the patients had previously resided. With regard to the notified cases of infectious diseases in London during 1894, it appears that the number of persons reported to be suffering from one or other of the nine diseases in the accompanying table was equal to 9.4 per 1000 of the population, estimated at 4,349,166 persons in the middle of the year. In the preceding two years the rates were 10.8 and 15.7 per 1000 respectively. Among the various sanitary districts the lowest rates were 5.1 in St. Martin-in-the-Fields and in Strand, 5.5 in Stoke Newington, 5.6 in Westminster, 5.7 in City of London, 6.2 in Hampstead and St. Giles, and 6.4 in St. James Westminster; the highest rates were 11.5 in Marylebone, 11.7 in Plumstead, 12.1 in Greenwich, 12.2 in Bethnal-green, 12.5 in Limehouse, 12.6 in St. George-in-the-East, 12.9 in Poplar, and 15.9 in Rotherhithe. The prevalence of small-pox in London showed a marked decline during 1894, the cases notified being 1192, against 423 and 2813 in the preceding two years; of these, 308 belonged to Marylebone, 113 to Poplar, 97 to St. Pancras, 85 to Bethnal-green, 84 to Islington, 45 to Mile End Old Town, 40 to Fulham, and 36 to Hackney. The number of small-pox patients admitted into the Metropolitan Asylum Hospitals during 1894 was 1234, and 16 remained under treatment at the end of the year. The prevalence of scarlet fever in London during 1894 showed a very marked decline, 18,446 cases being notified, against 36,901 during 1893; this disease was proportionally most prevalent in Limehouse, Mile End Old Town, Rotherhithe, Battersea, Greenwich, Woolwich, and Plumstead sanitary areas. During the year under notice 11,767 scarlet fever patients were admitted into the Metropolitan Asylum Hospitals; the number under treatment, which had been 2872 at the beginning of the year, was 1865 at the end of December last. Diphtheria also showed decreased prevalence during 1894, the cases notified being 11,186, against 5907, 8349, and 13,694 in the preceding three years; this disease showed the highest proportional prevalence in Bethnal Green, St. George-in-the-East, Limehouse, Mile End

MONTHLY ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING 1894.
(Specially compiled for THE LANCET.)

Sanitary areas.	Estimated population in the middle of 1894.	NOTIFIED CASES OF INFECTIOUS DISEASE.										DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.										Deaths of infants under one year to 1000 births.

† Including deaths from membranous group.

* Including 535 cases of membranous group.

Old Town, Poplar, St. Saviour Southwark, Bermondsey, Rotherhithe, and Greenwich sanitary areas. The Metropolitan Asylum Hospitals contained 293 patients at the beginning of 1894; 4128 new cases were admitted during the year, and 521 remained under treatment at the end of December last. Enteric fever was slightly less prevalent during the year under notice than in 1893; this disease was proportionally most prevalent in Bethnal Green, St. George-in-the-East, and Poplar. The number of enteric fever patients in the Metropolitan Asylum hospitals, which had been 103 at the beginning of 1894, was 104 at the end of December last; 675 patients were admitted during the year, against 623 and 734 in the preceding two years. Erysipelas showed the highest proportional prevalence in St. Pancras, St. Luke, Bethnal Green, Poplar, and Rotherhithe sanitary areas. The 253 notified cases of puerperal fever showed a decline of 144 from the number in the previous year; 24 belonged to Islington, 20 to Wandsworth, 17 to Greenwich, 16 to Lambeth, and 16 to Camberwell sanitary areas.

During the year under notice the deaths of 75,434 persons belonging to London were registered, equal to a rate of 17.4 per 1000, against 21.1, 20.3, and 20.9 in the preceding three years 1891-92-93. This rate was considerably lower than in any year on record, the nearest approach to so low a rate having been 18.0 in 1889. In the nine preceding years the London death-rate averaged 20.1 per 1000. In the various sanitary areas the lowest death-rates were 9.8 in Stoke Newington, 10.6 in Hampstead, 12.4 in Wandsworth and in Lee, 12.5 in Plumstead, 13.8 in Lewisham (excluding Penge), and 14.5 in St. George Hanover-square; the highest rates were 21.1 in Mile End Old Town, 21.4 in Whitechapel, 22.7 in Strand, 23.1 in St. George Southwark, 23.5 in St. Luke, 24.7 in Limehouse, and 26.4 in St. George-in-the-East. Taking the five groups of sanitary areas the rate of mortality during 1894 was equal to 16.1 per 1000 in the West, 16.2 in the North, 16.7 in the South, 20.5 in the Central, and 20.9 in the East districts. To the principal zymotic diseases 11,647 deaths were referred during the year under notice; of these, 3291 resulted from measles, 2637 from diphtheria, 2094 from whooping-cough, 1769 from diarrhoea, 961 from scarlet fever, 626 from different forms of "fever" (including 5 from typhus fever, 608 from enteric fever, and 13 from simple and ill-defined forms of fever), and 89 from small-pox. These 11,467 deaths were equal to an annual rate of 2.6 per 1000, against 2.3, 2.8, and 3.0 in the preceding three years 1891-92-93. Among the various sanitary areas the zymotic death-rates ranged from 0.9 in Stoke Newington, 1.1 in the City of London, 1.4 in St. George Hanover-square and in Hampstead, 1.7 in Lee, 1.8 in Wandsworth, and 1.9 in Lewisham, to 3.5 in Bethnal Green, 3.6 in St. George Southwark, 3.8 in Fulham, 4.1 in Mile End Old Town, 4.3 in Limehouse, and 5.0 in St. George-in-the-East. The 89 fatal cases of small-pox registered in London during 1894 were less than half the corrected average number in the preceding ten years; of these, 29 belonged to Marylebone, 8 to St. Pancras, 5 to Bethnal Green, 4 to Mile End Old Town, and 10 to Poplar sanitary areas. The 3291 deaths referred to measles were 659 above the corrected average; among the various sanitary areas this disease showed the highest proportional fatality in Fulham, Limehouse, Mile End Old Town, Poplar, St. Saviour Southwark, St. George Southwark, and St. Olave Southwark. The 961 fatal cases of scarlet fever were 140 below the corrected average; this disease was proportionally most fatal in Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, Greenwich, and Woolwich sanitary areas. The 2637 deaths referred to diphtheria were as many as 1150 above the corrected average; among the various sanitary areas this disease showed the highest proportional fatality in Paddington, Fulham, Bethnal Green, St. George-in-the-East, Limehouse, Mile End Old Town, St. George Southwark, Bermondsey, and Camberwell sanitary areas. The 2094 fatal cases of whooping-cough were 762 below the corrected average; this disease was proportionally most fatal in St. Giles, Strand, Shoreditch, Whitechapel, and St. George-in-the-East sanitary areas. The 626 deaths referred to different forms of "fever" were 68 below the corrected average; the highest "fever" death-rates were recorded in St. James Westminster and in Strand sanitary areas. The 1769 fatal cases of diarrhoea were little more than half the corrected average; among the various sanitary areas this disease showed the highest proportional fatality in St. Luke, St. George-in-the-East, Mile End Old Town,

St. George Southwark, and Rotherhithe. In conclusion, it may be stated that the mortality from measles and from diphtheria showed a marked excess in London last year, while that from each of the other principal zymotic diseases was below the average.

Infant mortality in London last year, measured by the proportion of deaths under one year of age to registered births, was equal to 143 per 1000, and was considerably below the average. The rates of infant mortality in the various sanitary areas ranged from 86 in Stoke Newington, 94 in Lee and in Plumstead, 113 in Hampstead, 114 in Wandsworth, and 115 in St. George Hanover-square, to 174 in Limehouse, 179 in Strand, 180 in Holborn, 185 in St. George-in-the-East, 186 in St. George Southwark, and 210 in St. Martin-in-the-Fields.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-CAPTAIN HALL has been posted to the North-Western and Surgeon-Captain Forde to the North-Eastern district on return from abroad. The following officers have arrived from India in the *Dilmara* on completion of a tour of service:—Surgeon-Majors Roche and Lewis and Surgeon-Captain Thacker. Surgeon-Major O'Sullivan has arrived in England from the Straits Settlements; Surgeon-Major Pike from Ceylon; and Surgeon-Captain Stiell from Egypt. Surgeon-Captain Kelly has embarked for Halifax. Surgeon-Captain Austin has been posted to Devonport on return from foreign service, and Surgeon-Captain Barefoot to Portsmouth, on exchange from Canada.

ARMY MEDICAL STAFF.

Surgeon-Lieutenant-Colonel Lewis Allen Irving to be Brigade-Surgeon-Lieutenant-Colonel, vice W. H. B. Clapp, M.D., retired.

INDIA AND THE INDIAN MEDICAL SERVICES.

The undermentioned officers of the Army Medical Staff, who are shortly expected to arrive in India from England, have been posted to the Bombay Command in succession to the officers named:—Surgeon-Lieutenant T. P. Jones, in succession to Surgeon-Captain R. Holyoake; Surgeon-Lieutenant E. W. Slayter, in succession to Surgeon-Major C. A. Webb; and Surgeon-Lieutenant C. O'Connor Hodgins, in succession to Surgeon-Captain S. F. Clark. Surgeon-Captain C. W. Johnson is appointed to the Collateral Charge of the Civil Surgeoncy, Meiktila, vice Surgeon-Captain T. W. Stewart, transferred. Brigade-Surgeon-Lieutenant-Colonel J. D. Gunning, A.M.S., having been permitted, as a special case, to return to England, tour expired, during the trooping season of 1894-95, will be detailed by the Principal Medical Officer H.M.'s Forces in India for duty with troops on the homeward voyage. The Queen's approval of the retirement from the Service of the undermentioned officers appears in the *London Gazette* of Jan. 18th: Surgeon-Lieutenant-Colonel Herbert Boyd, Bengal Medical Establishment; Surgeon-Lieutenant-Colonel Thomas Charles Howell Spencer, Madras Medical Establishment; Surgeon-Lieutenant-Colonel Patrick Murphy, M.D., Bombay Medical Establishment.

NAVAL MEDICAL SERVICES.

The following appointments are notified:—Surgeons and Agents F. J. Spilsbury at Anderly and Chapel, and Geoffrey Cross at Skegness.

VOLUNTEER CORPS.

Artillery: 1st Forfarshire: The undermentioned Gentlemen to be Surgeon-Lieutenants:—George Halley, M.B., and David Allan Carruthers, M.B. 1st Devonshire (Western Division, Royal Artillery): Surgeon-Captain John Tubb Thomas is appointed Captain. 1st Newcastle-on-Tyne (Western Division, Royal Artillery): Surgeon-Captain J. E. Norman resigns his commission. *Rifle*: 1st Volunteer Battalion, the Manchester Regiment: Surgeon-Lieutenant H. E. H. Matthews resigns his commission. 2nd Volunteer Battalion, the Highland Light Infantry: Surgeon-Lieutenant W. Sandeman, M.B., to be Surgeon-Captain.

VOLUNTEER MEDICAL STAFF CORPS.

The London Companies: John Robert Whait, M.B., to be Surgeon-Lieutenant.

VOLUNTEER OFFICERS' DECORATION.

The Queen has been pleased to confer the Volunteer

Officers' Decoration upon the undermentioned Officers of the Volunteer Force, who have been duly recommended for the same under the terms of the Royal Warrant, dated July 25th, 1892:—*North-Western District*: 2nd Volunteer Battalion, the Worcestershire Regiment: Surgeon and Honorary Surgeon-Major William Smith Batten, M.D., retired. *Western District*: 4th Volunteer Battalion, the Devonshire Regiment: Surgeon-Lieutenant Ezekiel Rouse. *Home District*: Rifle: 3rd Volunteer Battalion, the East Surrey Regiment: Surgeon-Major William Adolphus Fredk. Bateman. 1st Tower Hamlets Rifle Corps: Surgeon and Honorary Surgeon-Major John Hayball Paul, M.D., retired.

THE POST OF PRINCIPAL MEDICAL OFFICER OF H.M.'S FORCES IN INDIA.

We think that the Army Medical Staff is to be congratulated on the fact that the Secretary of State for India has refused to sanction the extension of service of Surgeon-Major-General Bradshaw, C.B., in the post of Principal Medical Officer of H.M.'s Forces in India beyond March next, when he will be retired. In stating this we have not, of course, a word to say against the qualifications and services of the officer in question. Our opinion is entirely based upon a matter of principle and considerations of justice to the medical department generally. The system of extension should, we think, only be very exceptionally had recourse to and in the interest of the public service only, because such extensions prejudicially affect the interests, of course, of many officers awaiting their promotion. We may fairly conclude that the Secretary of State for India does not see any exceptional grounds in India at the present time for departing from the regulations and usual procedure in such cases. Military matters are somewhat in a state of transition in India at present owing to the introduction of the new system of army organisation in that country. The changes that will ensue on Surgeon-Major-General Bradshaw's retirement will greatly depend upon who is to be the successor in his appointment. Surgeon-Major-General Walsh, the present principal medical officer of Madras, may presumably be appointed, provided he is desirous of extending his Indian service beyond five years and the authorities do not specially select some other officer for the post.

PROPOSED TESTIMONIAL TO SURGEON-GENERAL SIR JOSEPH FAYRER, K.C.S.I., Q.H.P., M.D., F.R.S.

At a meeting of the medical officers serving at Netley, held on Jan. 16th, Surgeon-Major-General Giraud, P.M.O., in the chair, it was unanimously agreed that a testimonial should be made to Sir Joseph Fayrer on his retirement as Physician to the Indian Council, President of the Indian Medical Board, and Member of the Senate of the Army Medical School. The testimonial will take the form of a portrait, to be painted by an eminent artist, and to be placed in the officers' mess at Netley, with a replica for Lady Fayrer. All members of the Army Medical Staff and Indian Medical Service are invited to subscribe, and contributions will also be received from other friends and admirers of Sir Joseph Fayrer. The subscriptions are not to exceed 10s. 6d. from each officer serving at home or in the colonies, or ten rupees from officers in India. The following officers have been elected as a committee to carry out the details of the presentation: Sir Wm. Mackinnon, K.C.B. (Director-General, A.M.D.), president; Surgeon-Major-General C. H. Giraud, A.M.S.; Deputy-Surgeon-General H. Cayley, F.R.C.S., I.M.S. (R.P.); Brigade-Surgeon-Lieutenant-Colonel J. L. Notter, M.A., M.D., A.M.S. (hon. treasurer); Brigade-Surgeon-Lieutenant-Colonel E. J. Fairland, A.M.S.; Brigade-Surgeon-Lieutenant-Colonel K. McLeod, M.D., I.M.S. (R.P.); Surgeon-Captain W. W. Webb, M.D., I.M.S. (R.P.) (hon. secretary).

AMBULANCE WORK FOR SAILORS.

We are glad to notice that a movement has been made for organising a system of first aid for sailors, who, from the circumstances in which they must necessarily be often placed, the injuries and accidents to which they are exposed, and their natural handiness and aptitude in helping sick people and one another, as well as their common sense, are well fitted to benefit by a plain practical course of instruction in this direction. Mr. A. M. Cato recently delivered an excellent lecture on this subject at Fishmongers' Hall, at the instance of the Shipmasters' Society and the St. John Ambulance Association, in which he pointed out the great need that existed among seafaring men for dealing with injuries and diseases at sea. He thought, and we agree with him, that lectures and practical instruction might be given

to sailors by surgeons at sea. A brief but interesting discussion followed the lecture, in which Sir A. Rollit, M.P., Sir Herbert Perrott, chief secretary of the St. John Ambulance Association, and others took part.

AID TO THE WOUNDED IN WAR.

Brigade-Surgeon-Lieutenant-Colonel Evatt recently delivered a lecture at Toynbee Hall, in which he described the existing army organisation of aid to the wounded, and traced out the method of their removal from the actual seat of war to the nearest field hospitals, and those in the rear or at the base, until reaching their final destination at Netley or other large hospitals in this country. The lecturer described the various stages, as laid down in the regulations of our own army on the subject and as practised in warfare at the present time, and he accompanied his description by such practical details and commentary as to afford his audience a succinct and useful account of the subject. The improvement in the system of aid to the wounded in war had, he declared, been enormous since the Crimean War and the time that Miss Florence Nightingale was at Scutari, but he desired to emphasise the necessity of keeping a sufficient number of helpers on the medical staff.

THE PILGRIM TRAFFIC.

The *Times of India*, in an article on the above subject, says that the British Government, having accepted the terms of the Paris Convention of April last, has thereby bound the Government of India to a convention which has been drawn up wholly on European lines without reference to Asiatic conditions. No doubt almost all the improvements that had been already suggested by the port health officers at Bombay have been insisted on by the Paris conference, even to the establishment of an International Board at Jedda, with power to control the pilgrim traffic from all parts of the world. So far so good; but in other directions it is feared that the Convention, as it now stands, will involve difficulties of a religious character, in that the expense of a journey to Mecca will be altogether prohibitive to a large number of the poorer Mahomedans, who will consequently be unable to make the Haj—a serious matter for the numerous faithful followers of Mahomet.

THE LADY DUFFERIN ZENANA HOSPITAL AT GYA.

The ceremony of laying the entrance stone of the Zenana Hospital of the Dufferin Fund at Gya was performed by Lady Elliott on Nov. 28th of last year in the presence of a distinguished European and Indian assembly. It is expected that the building will be ready in March next for the accommodation of twenty-five in-patients, with ample space for the treatment of out-patients. At present only a one-storied building is contemplated, but should funds permit a second storey will be added.

We have previously alluded to the services which Sir Joseph Fayrer has rendered the State and Indian Government during his long and distinguished career, and we are glad to notice that Mr. Secretary Fowler has taken the occasion of his retirement to refer officially to Sir Joseph Fayrer's services in eulogistic terms.

The promotion of administrative officers to the rank of Surgeon-Major-General will henceforth be carried out under the auspices of a specially constituted Promotion Board, of which a general officer commanding a district will be president and two Surgeon-Major-Generals members. We understand that the board will sit at a very early date.

The *Times* says: "It is stated that the War Office has decided to rebuild Winchester Barracks and to re-establish the rifle depot in that city. The work will probably occupy two years."

A new Dufferin Hospital, which has just been constructed at a cost of about Rs. 30,000, is about to be opened at Amraoti in Berar.

CATHOLIC UNIVERSITY MEDICAL SCHOOL: MEDICAL AND SCIENTIFIC SOCIETY.—The following office-bearers have been appointed for the session 1894-95: President: Mr. A. Roche. Vice-President: Dr. E. J. McWeeney. Hon. secs.: Mr. D. J. Coffey and Mr. J. A. Ringhan. Committee: Dr. A. Birmingham, Dr. O'Carroll, Mr. J. G. Gill, Mr. R. Farnan, Mr. J. Frengley, Mr. T. Donnellan, Mr. P. J. Dempsey, Mr. J. Gubbins, Mr. McArdle, Mr. J. P. McArdle, and Mr. J. M. Tighe.

Correspondence.

*"Audi alteram partem."***"THE GENERAL MEDICAL COUNCIL AND THE OBSTETRICAL SOCIETY."***To the Editors of THE LANCET.*

SIRS.—I am glad that Sir John Williams has drawn your attention to the astonishing resolution of the General Medical Council, dated Dec. 3rd, 1894. As an ex-president of the Obstetrical Society, and one who had much to do with the foundation of the society's examination for midwives, I had contemplated addressing you on this subject, but I refrained from doing so because I feared that in view of what seemed to me the outrageous coupling of the work of a scientific society such as the Obstetrical, even contingently, with such words as "infamous in a professional respect," I might have been tempted to write without the temper and moderation which Sir John Williams has shown. Had the General Medical Council taken the trouble to hear both sides of the question it could have easily ascertained that in instituting this examination the Obstetrical Society was acting from what, according to its lights, it considered the highest possible motives; that its examinations had been eminently successful; and that the society had only undertaken this work provisionally, and had frequently expressed itself as not only willing but anxious to discontinue it as soon as Government had legislated on the matter. Personally, I cannot see how the certificate granted can possibly be objected to; every year I issue a still more important-looking parchment to students who have achieved honourable mention in my class, which might quite as well be called a colourable imitation of a diploma. It appears pretty plain that "some enemy has done this thing," and that the Council has been thoughtlessly induced to lend a willing ear to the representation of the case put before it by the small but active section of the profession which aims at the impossible, and hopes to abolish midwives altogether. If the Council had done the Obstetrical Society the justice of pointing out in what way it wished its certificate altered there cannot be the slightest doubt but that its wishes would have received the most respectful consideration, and that the wording would have been immediately changed. Instead of doing this it fulminated, without any warning, the insulting resolution complained of. I am now told that the Council had directed some communication to be made to the society which it never received. If that is so, surely some explanation should be given of how such important documents were suppressed or failed to reach their destination.

I am, Sirs, yours truly,

W. S. PLAYFAIR.

George-street, Hanover-square, W., Jan. 19th, 1895.

"ISOLATION OF CASES OF OVARIOTOMY."*To the Editors of THE LANCET.*

SIRS.—Your correspondent, Mr. Malcolm, thinks it "most undesirable" to put ovariectomy patients in a general ward and gives his reasons for thinking so. He has been accustomed to the method of isolation, and he falls into the not uncommon error of concluding that the only right and proper practice is that in which he has been trained and which he has himself adopted. The fact is that the employment of isolation as a routine method is a relic of a bygone time, when ovariectomy was treated as something altogether different from other operations, when the peritoneum was regarded with an almost superstitious dread, and when, in our ignorance, we attributed our fatalities to atmospheric contamination instead of to our own surgical uncleanness. My experience at St. Thomas's Hospital has shown that the isolation of abdominal cases is, so far at least as regards hospital practice, as unnecessary as it is costly and inconvenient. I have at St. Thomas's Hospital only one separate ward, and that ward is single-bedded. When, owing to pressure of work, I began cautiously to try the effect of non-isolation, I did so in fear and trembling. All my prejudices then, like these of Mr. Malcolm now, were in favour of the older method. I soon found, however, that not only did no harm result from

its abandonment, but that the change brought with it a distinct gain to all concerned, to the patients themselves, to the nurses, and to the hospital. I encountered none of the dangers Mr. Malcolm fears. My experience of both methods is now considerable, extending to fifteen years of the older method and five or six years of the new. I still make occasional, though less and less frequent, use of my isolation ward for exceptionally severe cases and for cases that seem to be taking a markedly unfavourable course. For obvious reasons I never willingly let a death (after operation) take place in the general ward. This disposes of the one valid objection raised by Mr. Malcolm in the discussion to which he refers. I do not blame Mr. Malcolm for adhering to a practice with which he obtains successful results; but I do ask him, as a man who has proved his ability to think for himself and has shown himself to have a mind open to conviction, to suspend his judgment as to the comparative merits of the two methods until he has had experience of both. When he has, I venture to prophesy that he will come round to my way of thinking.

I am, Sirs, yours faithfully,

Brook-street, W., Jan. 19th, 1895. CHAS. J. CULLINGWORTH.

"THE ABSENCE OF SUGAR FROM NORMAL URINE PROVED BY A NEW AND SIMPLE METHOD."*To the Editors of THE LANCET.*

SIRS.—Dr. Pavy confidently asserts that "the fermentation process and the crystalline osazone production" prove that sugar is present in normal urine, and that all evidence to the contrary "goes for nothing." No physician, probably, has had larger experience of the fermentation test than Sir William Roberts, who says, "According to my experience urine containing 0.5 per cent., or two and a half grains to the ounce and under, yields no sign to the fermentation test."¹ Dr. Pavy states that he got a negative result with this test applied to normal urine until he was led to neutralise the acid urine by carbonate of soda; he then found that fermentation proceeded actively.² Now, one effect of adding carbonate of soda to acid urine would be to set free carbonic acid, and it would be interesting to know whether Dr. Pavy was careful to ascertain that the carbonic acid which was given off from the urine at a "suitable temperature" was not that which had been previously combined with the sodium. Dr. Pavy, as we know, by ignoring the reducing influence of kreatinine, estimates the amount of glucose in normal urine to be about 0.05 per cent., or a little over. Upon this estimate Dr. Noel Paton, Superintendent of the Research Laboratory of the Royal College of Physicians of Edinburgh, remarks:³ "This is in opposition to the recent most careful observations of Baisch,⁴ who finds that the sugar, ascertained after separation by its power on polarised light, amounts to, at most, 0.009 per cent., or, estimated by its reducing power, to 0.012 per cent. These results correspond closely to those of Seegen." Is it conceivable that the fermentation process would detect so small a proportion of sugar as this? There is the yet further question whether the reducing substance obtained by Baisch was not a product of the method employed for its separation from the urine.

Then, as to the phenyl-hydrazine test, Dr. Pavy assumes that the formation of osazone crystals affords conclusive evidence of sugar being present; but Dr. Noel Paton, in the paper above quoted, says: "The carbohydrates are not the only bodies which yield crystalline compounds with phenyl-hydrazine. A glance at Beilstein's 'Organic Chemistry' shows that a vast number of substances give such crystalline compounds." A consideration of the series of processes by which Dr. Pavy obtains the osazone crystals renders it highly probable that a reducing substance has—to use an expression of his own—"by a cleavage process been split off" from some constituent of the urine.

It will be seen, then, that the tests upon which Dr. Pavy relies to prove that glucose exists in normal urine are fallacious, while, on the other hand, the evidence which I have adduced proves conclusively that kreatinine, which

¹ Urinary and Renal Diseases, fourth edition, p. 210.² The Physiology of the Carbohydrates, p. 181.³ On the Physiology of the Carbohydrates: Edinburgh Medical Journal, December, 1894.⁴ Zeitschrift für Physiologische Chemie, Band xviii.

Dr. Pavy persistently ignores, accounts for the entire reducing action of normal urine upon picric acid, and for all the reduction upon ammonio-cupric oxide, which is not due to uric acid. In short, while the absence of sugar from normal urine is established by positive and indisputable evidence the supposed indications of its presence are not to be relied upon. I am, Sirs, yours faithfully,

Savile-row, Jan. 22nd, 1895.

GEORGE JOHNSON.

"INFANT NEGLECT, INSURANCE, AND MORTALITY."

To the Editors of THE LANCET.

SIRS,—In an annotation in THE LANCET of Jan. 19th you again refer to the practice of child life insurance and suggest the necessity for drastic reforms in a system of somewhat doubtful and limited advantage. Will you permit me briefly to draw the attention of your readers to a proposal in this connexion I made some time since, which was then submitted to the late Bishop of Peterborough? In the case of an infant or young child the one legitimate motive for insurance is to provide funds for its burial. This being so, what I propose is a short legislative measure prohibiting altogether infant life insurance by companies or firms, and empowering Government to enter into an agreement to inter any young child free of cost on the parents or guardians taking out a policy on its life and paying a small monthly premium at the nearest post-office. The working of such an arrangement would cost so little that all expenses could be met and decent burial secured for less than half the payments now made to insurance societies and burial clubs in respect of young children. However, economy is quite a secondary consideration; the main recommendation of my proposal is that in this way all possibility of temptation to neglect a child because it is insured for £6 would be done away with. Unfortunately, there are conditions in which such an apparently trifling sum represents a real temptation. I am, Sirs, yours truly,

FRANCIS VACHER.

Shrewsbury-road, Birkenhead, Jan. 22nd, 1895.

"THE DEBATE ON THE NATURE AND TREATMENT OF PERITONITIS AT THE OBSTETRICAL SOCIETY."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Jan. 19th Mr. Lawson Tait complains that he has been misrepresented and misunderstood in regard to his teaching on the question of the administration of purgatives after abdominal operations, and he refers to Mr. Frederick Treves as having fully expounded his views on the subject. Mr. Treves¹ quoted Mr. Tait to the following effect: "I have never said that the purgative treatment will cure peritonitis."² But in 1886 Mr. Tait wrote as follows: "Now we beat the peritonitis. On the slightest indication of peritonitis after an ovariectomy we give a rapidly-acting purgative, it matters not what; the patient's bowels are moved and the peritonitis disappears."³ In 1887 I published a paper⁴ in which I argued, and brought forward evidence to prove, that the symptoms referred to by Mr. Tait as "indications of peritonitis" were not necessarily due to that condition; that peritonitis was not the cause of the intestinal distension in the cases that were cured by purgatives; and consequently that peritonitis could not "disappear" in these cases. Since I published that paper I have seen no recommendation to treat peritonitis by purgatives in the writings of Mr. Tait. He has repudiated the practice and, as quoted above, he has asserted that he has never recommended this treatment. As Mr. Tait has again raised the question in THE LANCET I hope you will allow me to ask him for an explanation of the apparently contradictory quotations that I have cited from his writings. Two facts in Mr. Tait's position on this question, as restated in THE LANCET of to-day, should be carefully noted. In the first place he makes no distinction between the causes of abdominal distension in the cases under consideration—for instance, between obstruction of

the intestine and septic peritonitis, which have usually well-marked differences in their clinical symptoms. Such details are to him "pathologico-metaphysical conundra," for which he does not "care a fig." But they are important in practice, for by studying these questions and getting more knowledge about them the surgeon is able to avoid such errors as Mr. Tait fell into in 1886—namely, the empirical treatment of a symptom under a misapprehension as to its cause. In the second place Mr. Tait lays little stress on the dangers of purgatives administered by the mouth during the first few days after an abdominal section. This also is an important point in practice. Mr. Tait seems to be puzzled by the fact that "after a completed abdominal section symptoms and conditions may occur harmlessly on the ninth day which would be fatal on the fourth." The explanation is that on the fourth day the inflammation due to the operation has just passed its greatest severity, and a complication occurring at that time is an added burden to the patient; whereas by the ninth day the inflammatory fever may have subsided, and the vital powers of the patient have then only to deal with the complication. Hence the later any complication appears the less likely is it to exacerbate or rekindle an acute inflammatory fever, and as a consequence it is less dangerous to the patient in proportion to the length of time that has elapsed between the operation and its onset. I have elsewhere⁵ described at length how abdominal distension affects traumatic fever, but I suppose this is one of the "pathologico-physiological conundra" which have no interest for Mr. Tait. Nevertheless, this question has an intimate bearing on the practice of giving purgatives after an abdominal section. To get the patient over the first week of convalescence is of the utmost importance in abdominal surgery, and when intestinal distension occurs it is much the best practice to try to clear the bowel by enemata and to try to prevent further distension by keeping the stomach and upper intestine at rest. In this way the patient may be tided over the most dangerous period; whereas if a rapidly active purgative be given, as recommended by Mr. Tait, and if the bowels do not move, the distension is increased at a time when the patient is least able to bear the strain.

At the present day the most successful practice in abdominal surgery is directed to the prevention and removal of the causes of abdominal distension. The chief of these causes are septic peritonitis, obstruction of the bowels, and pseudo-ileus. The first is usually characterised by the well-marked facial change on which Mr. Tait lays so much stress. The other two are not so characterised. If cases in which there has been an injury to a hollow viscus and cases in which the peritoneum is left exposed are excluded, septic peritonitis may be absolutely prevented by the use of antiseptics. Ileus and pseudo-ileus should be treated after an abdominal section on the same principles as when they occur independently of an operation, and it is well known that purgation is a dangerous treatment of these conditions, and should only be resorted to with great caution, although sometimes it is brilliantly successful.

I am, Sirs, yours obediently,

Portman-street, Jan. 19th, 1895.

JOHN D. MALCOLM.

THE PUBLICITY OF MEDICAL EXAMINATIONS.

To the Editors of THE LANCET.

SIRS,—The General Medical Council devoted a great deal of time to visitation reports of examinations. The examinations reported on were all held at times and places well known to the Council and duly advertised to the public. They were in some instances presumably open to graduates or licentiates of the bodies. In some instances their doors were shut on those licentiates. For instance, the Dublin College of Physicians used to admit its diploma-holders to be present at its examinations, and their possible presence exercised a wholesome effect. That body now refuses to admit them, for last summer I applied in vain for admission. The pretext was that I should have been a Member of the College of Surgeons, whereas the converse pretext was not raised by the latter body. The illogical position of the Physicians would be seen at a glance. Now, Sirs, as Council visitors and inspectors cannot be in a dozen places at the same time, it would be a great protection both to the public and to the profession if the Council would make a law throwing

⁵ The Physiology of Death from Traumatic Fever.

open all examinations to the presence of every member of the profession. It is an utter waste of time and of money to be inspecting the recognised examinations when there are examinations of which the Council knows nothing and of which the public knows nothing—private special examinations, backdoors by which the black sheep of the flock can readily enter into the professional fold after they have been ignominiously rejected at the front door. It is absurd to be watching the front door while a back one is left open. I entreat your attention, Sirs, to this matter. Neither you nor the Council have the faintest suspicion of the abuses which flourish under it.

I am, Sirs, yours truly,

THOMAS LAFFAN.

Cashel, Jan. 7th, 1895.

THE TREATMENT OF EPILEPSY.

To the Editors of THE LANCET.

SIRS,—My attention has but recently been directed to the report in THE LANCET of Jan. 12th, of the meeting of the West London Medico-Chirurgical Society of Jan. 4th. I find I am therein represented as "referring to the benefits following the starvation treatment" of epilepsy (following the President in my use of this term). So far as I am concerned I am anxious to disavow the expression of such a view, my experience being that adequate nutrition is an essential to successful treatment. The view I advocated was, in truth, the utility of the substitution of an ample milk diet for one containing meat, for which, I submit, the designation of "starvation diet" is a misnomer. In my opinion advantage is derived, not only from the restriction of nitrogenous elements, which (according to some authorities) tend to the formation of unstable compounds in the nervous tissue favouring discharging lesions in the epileptic, but also from the avoidance of digestive troubles so often exciting an attack. In children especially, untrained in the Gladstonian method of mastication, who bolt imperfectly chewed masses of meat, the gain of a milk diet is great, as I had proof amongst the epileptic inmates of the Royal Albert Asylum, of which I was till lately medical superintendent. But the diet consisting of bread and milk, oatmeal porridge, farinaceous and custard puddings, with an ample supply of milk and eggs, was in no sense "starvation diet," the body weight usually increasing under the regimen. The discharging lesion of epilepsy appears, indeed, to depend upon nutrition being defective, not in quantity, but in quality; and Dr. Hughlings Jackson suggested long ago that "in the abnormal nutritive process producing unstable matter, nervous matter, the phosphorous ingredient is replaced by its chemical congener nitrogen." As regards drug treatment, borax in some cases seems to "act as a charm," but how to differentiate these cases is the difficulty. Regulated muscular exercise, especially in the open air (as in garden work), has, in my experience, been of more efficacy than drugs.

I am, Sirs, yours faithfully,

G. E. SHUTTLEWORTH, M.D.

Richmond, Surrey, Jan. 22nd, 1895.

THE LATE SURGEON-MAJOR PARKE.

To the Editors of THE LANCET.

SIRS,—As Provincial Deputy Grand Master of the Freemasons of North Connaught I would wish through your columns to inform those members of the profession who belong to the order that the Memorial Masonic Hall to be erected in Carrick-on-Shannon, the native town of the late deeply lamented Surgeon-Major Parke, has not as yet been commenced owing to the funds collected being insufficient for the purpose. I feel certain that every member of the medical profession would wish the name of one whose services both in the field and with the Emin Pasha Relief Expedition were so distinguished should be permanently kept in memory, and this being distinctively a Masonic memorial I would ask physicians and surgeons being Freemasons to contribute. Small donations will be thankfully received, and may be sent to me or to Surgeon-Lieutenant-Colonel Bradshaw, Carrick-on-Shannon. Further lists of subscribers will be published, and all subscriptions duly acknowledged.

I am, Sirs, yours faithfully,

FRANCIS E. CLARKE, M.D., M.R.C.P.I.
Boyle, Ireland, Jan. 17th, 1895.

PROPOSED ASSOCIATION OF QUALIFIED MEDICAL ASSISTANTS, JUNIOR MEDICAL OFFICERS, AND LOCUM-TENENTS.

To the Editors of THE LANCET.

SIRS,—It has occurred to me that such an association as the one proposed would be found to be very advantageous to gentlemen filling above appointments, and with this object in view I venture to state briefly some of the questions which might be settled by such a powerful organisation as this association might in time become if properly and rightly managed:—1. In connexion with this association I would suggest the formation of a special department, styled the "Medical Bureau," to take the place of the present private medical agencies, whereby members of this association might, by subscription or otherwise, possess the means at reasonable charges for obtaining suitable appointments. 2. The question of salaries paid to qualified assistants: (a) mode of treatment by principal or committee; (b) terms of engagement and dismissal; (c) contracts or covenants not to practise. 3. The "social" status of the qualified assistant should be fairly recognised as a legally appointed medical man. 4. Discontinuance of employment of unqualified men as medical assistants, and the results therefrom: (a) more openings for the qualified man; (b) therefore less needy men in our ranks ready to jump at any poorly paid office; (c) in every town where there are sufficient qualified chemists I would suggest that every practitioner should employ such to dispense his medicine; (d) such a plan as this would leave a field of labour open to the unqualified assistant, as his services might be used by chemists; (e) and in case medical men ceased to countenance or even employ unqualified men, then chemists should be compelled to give up prescribing as they do now. 5. I further think as a sound basis such an association should possess some code of ethics, so that each new man in the profession should become intimately acquainted with the true meaning of medical etiquette, which to my mind is the ground-work of all real proper feeling and treatment of one medical man to another. And, lastly, if these matters were carried out I venture to think in time we should gradually find our profession would take its proper and legitimate position in the world as a truly scientific calling, and not as the miserable trade which many make it.

I am, Sirs, yours truly,

T. HOWARD BROCKLEHURST, M.R.C.S. Eng., L.S.A. Lond.
Westham, Weymouth, Jan. 23rd, 1895.

* * It will be noticed that we have adopted Dr. Donkin's suggestion (vide THE LANCET, Jan. 12th, p. 120) with regard to a practical "plural of locum tenens."—ED. L.

THE ÆSCULAPIUS LODGE.

To the Editors of THE LANCET.

SIRS,—Gladly as would be welcomed amongst all good Masons any lodge bringing closer together members of the profession, I venture to suggest that the lodge in process of formation in connexion with St. Bartholomew's Hospital, as reported in THE LANCET, cannot be held to be quite on parallel lines with those of the three universities—Oxford, Cambridge, and London—or even with the Bar Lodge. The claim to such a distinction rests with the Æsculapius Lodge, now in its fourth year of existence, since we number not only members of a particular hospital, but of the whole medical profession wherever educated throughout the British Empire.—I am, Sirs, your obedient servant,

Portland-place, W.,
Jan. 19th, 1895.

THOMAS DUTTON,
Secretary, Æsculapius Lodge.

"THE SUPPORT OF HOSPITALS."

To the Editors of THE LANCET.

SIRS,—With reference to an annotation which appeared in THE LANCET of Jan. 12th, dealing with the financial condition of our hospitals and taking the case of Charing-cross as a text, I should like to make a few remarks.

It is especially of importance that those interested in the immediate working of a hospital should look most carefully into every detail of its management and see that its claims

are properly represented, not only to the inhabitants of the neighbourhood, but also to the public at large. It should not be left to a few well-known generous supporters of a hospital to make up a heavy deficit, but general pecuniary aid should at once be invoked. This reflection must arise in thinking minds whether, as hospitals at present seem to have to rely for their support mainly upon local aid, certain districts of London are not overdone with these institutions. A tradesman in Leicester-square, for instance, may, under the existing state of things, be expected to contribute to St. Thomas's, Westminster, Charing-cross, or King's College Hospitals, while a man who is run over in Parliament-street has his choice of at least three admirable hospitals within easy reach. Many poor people come to each of these hospitals from districts which hardly contribute one penny to the support of any of them, and drain the funds, which the more prosperous inhabitants of their neighbourhoods never dream of augmenting. I believe that the crowding of hospitals in one locality, due to the necessity of an accessible position for the medical schools, is a serious reason of the difficulty of supporting them, when, as is now the case, their claims are only known to the few in their immediate neighbourhood. I cannot doubt that a general hospital opened in such a district as Battersea or Camberwell would not only obtain good support, but would perform most useful work and be crowded with those forms of disease, especially surgical cases, which admit of such ready relief and are of such importance for medical study. We are all agreed that the function of hospitals as centres of medical education for students is one of the first national importance, and, while this is becoming seriously imperilled by the establishment of special hospitals in all parts of London, I do not see why local general hospitals should not be splendid centres of education. The special hospitals not only take away the cases most useful for medical instruction, but also attract not a small proportion of the funds which should flow to the larger institutions.

But these and kindred matters, including the chaotic state of London with regard to its charities and modes of medical education, while I am certain that they are yearly ripening for Government interference, are without the object of this letter, which is to urge upon the inhabitants of the different localities of the wealthiest city of the world the paramount and immediate necessity of rallying to the support of hospitals associated with teaching schools, now languishing for want of funds.—I am, Sirs, yours faithfully,

ASSISTANT SURGEON TO A GENERAL HOSPITAL WITH
Jan. 21st, 1895. A SCHOOL AND WITHOUT PAY WARDS.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Society of Chemical Industry.

AT the last meeting of this society a paper was read by Mr. Le Neve Foster on the Prevention of Smoke arising from Intermittent Firing in various processes of Chemical and Allied Industries. Some members of the Sanitary Association were invited to the meeting, and the vice-chairman of the Sanitary Committee of the corporation. Mr. Le Neve Foster said that in these days of foreign competition economy was essential, and the combustion of coal was the best and cheapest way of producing heat. With regular firing smoke could be avoided almost entirely, but in chemical works the firing was irregular. In most operations the apparatus had to be cooled on their completion; and before recharging "the fires had to be started *de novo* in order to heat a mass of cold brickwork and flues, entailing great difficulty in preventing the emission of black smoke." In spite of difficulties, however, much might be done by each individual manufacturer by strict supervision and careful construction of plant. This was shown in his own works, where the emission of black smoke had been reduced to an average of thirty-three seconds per hour. No doubt in some cases praiseworthy efforts had been made to minimise nuisances, both as to smoke and noxious fumes. In the main the discussion after the paper was disappointing, the speakers dwelling more on the difficulties of smoke prevention and on the terrible consequences that would follow any interference by the authorities rather than on the remedial methods suggested, in which, indeed, little interest was shown. The Chairman (Mr. Forbes Carpenter, a Govern-

ment inspector of practical and scientific eminence) mentioned one method which had been found successful; but it was not alluded to by any of the speakers, nor was another, seen in practical use in Germany, which was described by another member of the society. The impression left by the discussion was that much more might be done to lessen the emission of black smoke without injury to the manufacturers, and, of course, with corresponding advantage to the rest of the community, who now, for their sakes, suffer so much in comfort, health, and pocket.

Ladies' Health Society.

The annual meeting of this society was held recently in the Lord Mayor's parlour at the town hall. The Lady Mayoress occupied the chair, and the audience, composed chiefly of ladies, was very large. The meeting, indeed, compared with similar meetings of other philanthropic societies, was, as regards audience, a great success. The more than usual interest shown may perhaps in part be due to an elaborately organised charity ball having been recently held in aid of the funds of the society. It was a most skilful and, I may surely say, praiseworthy mode of advertising the society among those able to give efficient help, and was eminently successful both socially and financially, the proceeds clearing off a considerable debt. Notwithstanding this, however, more subscriptions are wanted, for the year's work left a deficit balance of £127. Yet this is one of the most useful philanthropic agencies we have, which has for thirty years past done quiet, practical, unostentatious work that cannot be done by men. In its beginning a few ladies distributed tracts and leaflets on health topics; for the ignorance of the poor on sanitary matters had impressed itself on the late eminent surgeon, Mr. Turner, and he suggested this mode of spreading such knowledge among the poor. About the year 1879 the late Bishop Fraser drew attention to the system of visiting among the poor of Elberfeld, and a scheme for visitation was welcomed by the ladies of the society as in some measure tending to lessen one of the great evils of modern manufacturing life—the separation of rich and poor, of employers and workpeople. The latter had become massed together in the near neighbourhood of the factories and workshops, while the former, with their wives and daughters, betook themselves further and further away from the dirt and smoke of the town. This scheme led to the employment of respectable, intelligent working-class women as health visitors under the supervision of the ladies. Districts are assigned to a health visitor, who goes among the people constantly, and is immediately responsible to the lady in charge of the district, with whom she is in frequent communication. The health visitor can understand the difficulties of the poor better in many cases than the lady, and is also less liable to be imposed on. The lady visits the district at least once a week, if not more frequently, and holds a weekly mothers' meeting, at which simple addresses are given and conversations held on such subjects as personal and household cleanliness, thrift, ventilation, the prevention of infection, the care of children, the feeding, washing, and dressing of infants, cooking and nursing, the making and mending of clothing, &c. The lady visitor is often accompanied by one or two young friends, who vary the proceedings with music and singing. The health woman is always present at these meetings, and in going her rounds afterwards can afford practical help in carrying out some of the hints given at the mothers' meeting. At present there are about twenty districts in Manchester and Salford, with twenty health women and about forty ladies engaged in this work, but there is room for more. Both corporations avail themselves of the help of the society in the superintendence of some women employed by them in similar work, with satisfactory results. This movement owes much of its success to the courtesy and enthusiasm of Dr. Tatham, the late medical officer of health. The great merit of the plan is that direct personal sympathy and help in domestic and sanitary matters are brought to the homes of the people. The meeting illustrated the fact that women, even in the most staid society, are throwing off the fetters of the old conventions. The chair, as already stated, was taken by the Lady Mayoress, who spoke very well, as did also two ladies who proposed and seconded a vote of thanks to the Lord Mayor and Lady Mayoress. Each gave interesting accounts of experiences as lady visitors, which showed the great value in many ways of personal intercourse with the poor. The meeting ought to be followed by an increase of subscribers and especially of lady workers.

Paupers' Tea and Food.

The Salford guardians are contemplating a revision of the workhouse dietary, and according to statements made in the *City News* last Saturday it might be more liberal without being lavish. In a previous issue a statement was made, from information received, that common soda was used in making the tea. This was denied, but "nothing was said last week at the meeting of the guardians about the quantity of tea used for a brew. We put this at one ounce to eight pints of water, say three-farthings' worth of tea to a gallon of water, or one-tenth of a penny per pint. Sugar is added, but no milk." "This is but a sorry beverage for the aged and infirm," with which opinion many of us would agree. The bread is said to be buttered, but while there is no butter on the list of provisions, 18,000 lb. of margarine are supplied at a trifle less than sixpence a pound, or three-eighths of a penny per ounce. According to the diet table at another workhouse half an ounce of this condiment is allowed at breakfast and supper, at a cost of about three-sixteenths of a penny a meal. In the same article the daily cost of the food of a grown-up woman, calculated from the tables of the Prestwich workhouse, is three-halfpence. Breakfast and supper are alike, and the menu is five ounces of bread, a pint of tea, and half an ounce of margarine. Dinner consists of a pint and a half of soup, with five ounces of bread. The soup is said to be "very thin" and the full quantity not always given. Last year's provisions for the Salford workhouse included 2764 lb. of tea. There are over 1300 inmates, so that in round numbers there would be 2 lb. per head, or three-quarters of an ounce a week. After considering the share that would fall to the men and the children, the article goes on to say: "Reckon as we like, the amount cannot be more than an ounce and a quarter a week, and for this the women have the liquid fourteen times a week, a pint each time." The conclusion this paper comes to is that in many of our workhouses the actual eating and drinking do not cost more than 10d. a head per week. This shows great—almost too great—regard for the ratepayers, and one is not astonished to read that the following remark is common among the old women: "We can manage somehow with the food, but the tea is a great trial to us."

Jan. 22nd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Small-pox in Edinburgh and Leith.

LAST week seven fresh cases of small-pox were reported in Edinburgh and two in Leith. Of the deaths during the week in Edinburgh two were from small-pox.

The late Dr. Robert A. Goodsir.

Dr. Robert Anstruther Goodsir died in Edinburgh in the end of last week at the age of seventy-one. He was a brother of the eminent anatomist who shed so much lustre on the University of Edinburgh in the earlier half of the century. Another brother, also a medical man, accompanied Sir John Franklin's fatal expedition to the Arctic regions in 1845; and this was the motive which led Dr. Robert Goodsir to make two expeditions to those regions. In the second expedition he went as surgeon to the ship fitted out by Lady Franklin to search for her husband. Some time after returning from the Arctic regions he went to Australia, and there led the active, restless, and exciting life of an up-country squatter. He travelled much in Asia and elsewhere, and returned to Edinburgh about ten years ago.

The Edinburgh Medico-Chirurgical Society.

It has been intimated that at the February meeting of this society Professor Fraser is to open a discussion on Cardiac Therapeutics. It is anticipated that the discussion will be an interesting one, and will be a further addition to the valuable series of discussions this society has had during the past few sessions.

Conversazione at the Royal College of Physicians of Edinburgh.

Invitations have been issued by the President of the Edinburgh Royal College of Physicians, Professor Gairdner, and Mrs. Gairdner for a conversazione to be held at the College on Feb. 8th.

The Health of Aberdeen.

Dr. Matthew Hay, in his monthly report, states that the registrar's returns for December give a total of 285 deaths in the city, equal to an annual rate of 25.49 per 1000. This high rate is mainly due to the prevalence of measles. The mean age of all persons dying during the month was 21.8 years, as against 26.2 in the preceding month and 35.6 in the corresponding month of last year. This is one of the lowest recorded in recent years, and is due to the high infant mortality from measles. The mortality rate of children under five years is nearly twice the average rate for the corresponding month in the preceding ten years. Compared with the corresponding month in the preceding ten years, the past month exhibits a total death-rate which is higher than the average by nearly 14 per cent., and is also higher than in any individual year in the decennium except 1884, when the rate, partly owing also to an outbreak of measles, was as high as 28.97. The total number of zymotic cases reported during the month was 1223, with 54 deaths, as compared with 384 cases, with 23 deaths, in the preceding month. There are no further cases of small-pox; cases of scarlet fever, whooping cough, and erysipelas have declined; typhoid fever is stationary; diphtheria has increased considerably, 16 cases with 5 deaths having been reported; and measles has increased enormously, 1102 cases with 39 deaths having been reported, as against 251 cases with 5 deaths in the preceding month. The following is the return of cases of zymotic diseases notified during the past week: measles, 204; scarlet fever, 5; diphtheria, 5; typhoid fever, 1; whooping-cough, 7; erysipelas, 7; total cases, 229—being a decrease of 133 on the whole as compared with the previous week. The decrease is mainly in measles, but there is also a decrease in scarlet fever and typhoid fever. There are no cases of small-pox, typhus fever, or puerperal fever.

Public Health in Glasgow.

The most notable feature in the city's health condition just now is the slight spread of small-pox. In all, eleven cases have been reported, the entire series being traceable to contact with the four cases referred to in this column a fortnight ago. One death has occurred and some of the patients—particularly those who had not yet undergone revaccination—are dangerously ill. In connexion with this outbreak the authorities have very properly revaccinated the prisoners detained in the various local prisons, and, one of the prisoners having died some time after, it was alleged that the revaccination had been the cause of death. A post-mortem examination, however, showed that the patient had died from pneumonia and pericarditis, while the arm in which the lymph had been inserted was in a perfectly healthy condition. The health authorities are thus more than ever satisfied that in revaccinating the inmates of the city prisons they are taking a necessary and efficient precaution against the spread of a loathsome disease among those of the populace who really need it most.

The Duke of Argyll.

Dr. McCall Anderson is able to report favourably of the progress of the Duke of Argyll. On Thursday the temperature was generally normal, and although indigestion remained he showed a fair appetite, while the pulse was regular and stronger.

Jan. 24th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Dublin Hospital Sunday Fund.

THE returns for the Dublin Hospital Sunday Fund collections made last November are now to hand. The total collections, donations, &c. for 1894 amounted to £4323 15s. 7d., or an increase of some £93 as compared with 1893. Included in the amount was a sum of £55 18s. 5d., the proceeds of a football match, and £44 18s. 11d., the proceeds of an international lawn tennis match.

The Battle at Cork.

The battle of the clubs proceeds apace. Two other medical men came to town last week, making a total of four whose services are now at the disposal of those clubs whose members still think that they and their families should be treated for an entire year at a lower rate than 7s. 6d.

and 15s. when the member's income is under £100 and £200 respectively. Judging from the proceedings of the Queen-street Benefit Society, the clubs now consider that the four medical men they succeeded in bringing together represent a plethora of medical material, for I find one of the members of that society last Friday night solemnly warning his fellow members that the executive committee of the society delegates "had decided that three doctors were the most that the Cork societies could support." What a sad reflection—one of the four must go. For the sake of the Cork societies he despised the public opinion of the whole profession in the United Kingdom and was prepared to be ostracised by the medical men here. Yet what has been his reward for such disinterested services. The clubs simply tell him they will not have him, and he is left to his own devices to procure the fare to take him back to wherever he came from. Magnanimous and characteristic action of the Cork clubs to a member of the medical profession. The secretary of the St. Nicholas Club has resigned, and I have reason to believe that many of the members intend to follow his example. The Queen-street Society numbers some sixty or eighty members, and only twenty-seven of those took the trouble of recording a discriminating vote for one of the two competing imported medical men. Even more remarkable still, the Central Hull Society numbers some 100 members, and only seventeen of them voted last week at an election of a medical man, so little did the general body care which of the strangers obtained the appointment. A very sensible letter, too, appeared in the papers urging that a new society should be formed to embrace the many from the various societies who would be quite willing to accede to the medical men's terms. With these and other indications before me I cannot help feeling that victory is bound to be on the side of the medical men and that the end is approaching. It may be somewhat slowly, but all the same certainly and surely. I should mention that a curious development of the dispute took place last week. The medical students had previously been silent spectators of the struggle; but when they found that a gentleman who had been educated at the Cork Queen's College, and was quite recently a fellow student of theirs, had returned to the city to oppose his former teachers the students became very irate, and especially so when they saw by the newspapers that he used, in opposition to the interests of professors, hospital physicians, and surgeons, the very testimonials which those gentlemen had previously given him. Accordingly the students held a mass meeting and passed resolutions expressing sympathy with the local medical men, condemning the action of the strangers who had come to support the clubs, and declaring that any students holding intercourse with the latter should be expelled from all college clubs. This action of the students shows that there is a very strong and very commendable *esprit de corps* amongst the *alumni* of the Cork College, and some gentlemen holding medical qualifications would do better if they were guided by the same code of honour as the Cork students. After the termination of the meeting the students marched to the residences of various city medical men, cheering for the latter, and afterwards relieved their pent-up feelings by hissing and groaning outside the apartments occupied by the new club medical officers. The police were present in the interests of the latter, but the students had too much self-respect to think of doing anything calculated to require the intervention of the constables. However, the latter considered it more prudent to mount guard all night, and I have no doubt even the most junior of the newcomers finds that, at least under some circumstances, a "doctor's" life is not a happy one.

Nerwy Dispensary.

On Jan. 16th, at a meeting of the Nerwy Dispensary Committee, Mr. Henry W. Smartt was appointed medical officer for Nerwy No. 1 District, in the room of the late Mr. Andrew McBride, at a salary of £120 per annum as medical officer and £25 per annum as medical officer of health.

Queen's College, Belfast.

On Jan. 16th Dr. W. H. Thompson, Danville Professor of Physiology, began his course of lectures on health, which are free to the public. There was a very large attendance, the subject being the skin and its relation to health. In conjunction with the Gilchrist Lectures Committee the Society for the Extension of University Teaching has arranged that Professor Letts shall deliver six lectures on Chemistry, with special reference to Belfast Industries. The first lecture,

which was on Air and Water, was delivered on Jan. 17th in the Grosvenor Hall.

Belfast Hospital for Consumption and Diseases of the Chest.

At the annual meeting of the friends of this hospital, held on Jan. 16th, the honorary secretary of the medical staff, Dr. Howard Sinclair, reported that there had been 758 extern and 88 intern patients during the past year. It is satisfactory to find that the subscriptions have increased from £490 in 1893 to £605 in 1894. The endowment fund has been increased by donations of £164 11s. 8d., and the building fund has been increased by £1117 10s. 11d.—in other words, all the accounts show an increased revenue.

The Samaritan Hospital, Belfast.

The medical report submitted to the annual meeting held on Jan. 21st showed that there had been 501 extern patients during the year, while there were 106 treated in the wards. Sixty-six operations were performed, twelve of these being abdominal sections. The mortality was 3 per cent. for the year. While a large number have availed themselves of the advantages of the institution, it is regrettable to note that there has been a falling off in the list of subscriptions. This, however, may be due to the dullness of the times, as all charitable institutions have suffered. Several speakers spoke of the good done in the hospital and of the need of obtaining more subscribers.

Death of Mr. Henry, F.R.C.S. Edin., Pomeroy.

One of the oldest and most respected north of Ireland practitioners, Mr. Henry of Pomeroy, county Tyrone, died at his residence on Jan. 19th, at the advanced age of seventy-nine, and was buried on Tuesday last. Mr. Henry, who was a Fellow of the Royal College of Surgeons of Edinburgh, practised for a lengthened period at Pomeroy, county Tyrone, where he enjoyed the complete confidence of the public. He was a man respected alike for his kindness, ability, and high character, and enjoyed a large practice.

The Belfast Royal Hospital.

The working men's committee have just published their report of another year's work. The subscriptions from those engaged in various places of employment have reached the sum of £2371 4s. 1d., an increase of £210. These figures show that, since the committee was formed, the annual income to the hospital from this source has increased by over £800. What is very gratifying is that not only have the subscriptions increased, but the number of places contributing has also increased. As to the work done in the hospital, one out of every twelve of the inhabitants has received treatment in some form during the past year, and over 90 per cent. of these belong to the working classes. A pleasing feature in the report is the feeling of entire confidence expressed in the Royal Hospital.

At a recent meeting of the trustees of the South Infirmary, Cork, Dr. John Reid was elected house surgeon and Dr. R. P. Crosbie assistant house surgeon respectively.

Dr. Charles Mayne, visiting surgeon to the workhouse at Loughlinstown, Rathdown Union, county Dublin, has resigned his appointment owing to continued ill-health.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Sero-therapy as a Remedy for Syphilis.

MM. HÉRICOURT and RICHET, whose names will be familiar to the readers of THE LANCET in connexion with the sero-therapeutic treatment of tuberculosis, have been extending their experiments to other diseases. Four years ago injections of dog's serum were employed, at their instigation, in the wards of Professor Fournier against lupus and syphilis rebellious to ordinary medication. In two cases of syphilis unamenable to specific treatment dog's serum quickly transformed the general condition and paved the way for an efficacious application of ordinary specific treatment. The cases were as follows. A woman aged fifty years, to whom syphilis had been communicated by her husband twenty years previously, became, ten years after infection, neurasthenic and had osteoscopic nocturnal pains. Two years before admission into Dr. Fournier's wards she had an attack of iritis, and her walk became incoördinated

Specific treatment was found practically useless, as also was the employment of Brown-Séquard's method. Injections of inoculated dog's serum brought about in a week (three injections of 6 c.c. were made during this period) considerable improvement—the nocturnal pains and the lightning pains in the lower limbs from which she had suffered became almost inappreciable in intensity. This result would appear to indicate a method of treatment for ataxia of syphilitic origin. The other case was that of a woman aged twenty-five years, syphilitic for three years. When admitted she had numerous ulcers, reminding one of the aspect presented by cicatrising gummata. These lesions had existed for six months. Daily injections for one week were made of from 1 to 3 c.c. (22 c.c. in all) of prepared dog's serum. On the seventh day of treatment febrile urticaria developed, and vertigo was complained of. The treatment, commenced on Dec. 10th, determined in the ulcers a cicatrising action, apparent on the 14th, and recovery was on the 18th nearly complete. At the same time the woman gained flesh and lost her anæmia.

The Number of Medical Men, Dentists, &c. in Paris.

The Prefecture of Police will shortly issue a report giving the number for each arrondissement of medical, dental, and obstetric practitioners, and of pharmacists practising in this capital. It appears that on Dec. 31st, 1894, the list was as follows: Doctors in medicine, 2153; officiers de santé (now obsolete) 84; midwives (*sages-femmes*), 1090; chemists, 960; surgeon-dentists, 69. It must be understood that the 69 dentists only include those persons who have, since the promulgation of the new Medical Act in December, 1892, taken their diplomas. The bulk of the dental practitioners of Paris practise in virtue of a clause of the Act empowering such of them as had paid a patent for the year ending December, 1893, to continue their avocation. Medical practitioners are very unequally distributed amongst the twenty arrondissements. Thus, the eighth arrondissement, with a population of 91,000, possesses 385 medical men, or 1 in 235, whereas the much more populous twentieth arrondissement (population 130,000) boasts of only 29, or 1 in 4500.

The General Result of the Antitoxin Treatment of Diphtheria.

A survey of the statistics hitherto published in divers countries of the results of the application of Behring and Roux's method in the treatment of diphtheria up to the last day of December, 1894, gives a total of 2700 cases with 433 deaths, or a mortality of 16 per cent.

The Sterilisation of Drinking Water.

A very simple and efficient method of sterilisation of water is highly recommended by M. Meillère, Chemist-in-Chief of the Academy of Medicine. Four drops of the tincture of iodine of the French Codex sterilises in a few minutes one litre of spring water, all pathogenic micro-organisms being destroyed. For ordinary household use M. Meillère states that the best method of sterilising water is to prepare with it an infusion of tea, limes, or hops; but the iodine method may, he says, be advantageously employed by travellers.

Mr. Victor Horsley.

Our distinguished compatriot, Mr. Victor Horsley, was on the 16th inst. elected a foreign corresponding member of the Société de Chirurgie—a fresh proof of the esteem in which he is held by the profession in France.

Congress of Aliénists.

The Sixth Congress of the Alienists and Neurologists of France and French-speaking Countries will be inaugurated at Bordeaux on Aug. 1st, under the presidency of Professor Joffroy, the successor of the late regretted Professor Benjamin Ball in the chair of Mental Pathology at the Paris Faculty. The programme will include discussions on the following subjects:—Thyroid Gland and Exophthalmic Goitre—reporter, Dr. Brissaud; the Psychoses of Old Age—reporter, Dr. Ritti; the Medico-legal Aspects of Epileptic Impulsions—reporter, Dr. Partant. Excursions, visits to asylums, and a banquet will complete the doings of the congress, which has for its secretary a former pupil of Professor Ball—viz., Dr. Régis of Bordeaux.

Jan. 22nd.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Public Health Items.

DURING the year 1894 there were, in the province of Ontario, fifteen outbreaks of small-pox, comprising thirty-five

cases, six of these proving fatal. This must be considered a most satisfactory record, especially when it is remembered that in the States to the west of us it is quite prevalent. According to reports received from the local boards of health diphtheria occurred in 110 municipalities, the total number of cases being 369, with 28.1 per cent. of deaths. Since the introduction of antitoxin the Provincial Board of Health has been in the receipt of weekly supplies from the New York Biological and Vaccinal Institute, averaging 500 c.c., which have been distributed by Dr. Bryce through the province where most needed. So far some hundred cases have received the treatment; blank forms for the systematic reporting of cases have been adopted by the board with a view to their being subsequently reported upon when a large number have received treatment.

Treatment of the Insane in British Columbia.

The report of the Royal Commission appointed to investigate the Provincial Insane Asylum at New Westminster has recently been laid before the Legislature, and from the reports to hand it would seem that the treatment received by the unfortunate inmates was not in many particulars along the line of "modern treatment"; the institution is said to be equipped with implements of mechanical restraint or punishment such as handcuffs, leather mitts and muffs, steel anklets, leather anklets for women, pinion straps, and strait-jackets. Besides the use of the foregoing there was a system known as the "ducking" or "cold dip." One clause in the Commissioners' report is given in the *Mail* of Dec. 22nd as follows: "We were astounded at bearing patient after patient telling the same stories of inmates being thrashed with straps, of their being kicked, handcuffed for trifling offences, struck with the fist, ducked in cold water until nearly suffocated, of their being tortured by semi-strangulation by means of the strait-jacket, and of one man having a hand crippled for life by the prolonged use of a leather mitt." I cannot help thinking that some amount of exaggeration may have crept into the evidence due to the mental condition of the inmates, but nevertheless the fact remains that severe measures have been adopted and carried out in some cases to the point of cruelty, and I hope to hear of speedy reorganisation of the management.

Accident at Beaconport Asylum.

While visiting one of the wards of this asylum recently Dr. Volee, the chief medical superintendent, was suddenly felled by a blow from a piece of iron pipe in the hands of an inmate. I believe I am correct in saying that he has since succumbed to the injury. Had it not been for the action of an attendant he would have been instantly killed.

Canadian Weather.

As evidence that we are not perpetually wrapped in snow and ice the following items from the report of the Meteorological Department for December, 1894, may be interesting. The mean temperature was 31.28° F., being 5.06° higher than the average for fifty-four years. The highest temperature (49.3°) occurred on the 16th and the lowest (6° below zero) on the 28th. On each of twenty-five days the mean temperature was above the average of that particular day and below on six days. The mean humidity was 80; the mean amount of cloud was 69, being 8 below the average; and there were 77.4 hours of direct sunshine out of a possible 277.3. Rain fell on eleven days to the depth of 1.895 in. and snow on seven days to the depth of 2.2 in.—i.e., 11.9 in. below the average. From this it will be gleaned that we have been enjoying an open winter.

THE PASTEUR-CHAMBERLAND FILTER.

THE remarkable stand which the Pasteur-Chamberland filter is making against the most severe and searching tests is a fact which in the interests of hygiene cannot be ignored. It would seem almost unnecessary, indeed, to institute further investigation, since it affords, as is well known, a reliable instrument in the bacteriological laboratory for the sterilisation of cultures, or for removing organisms from other fluids as in the preparation of antitoxin. For this purpose it is looked upon to accomplish this end as a matter of course, just as the fine paper filters which are to be found in every chemist's laboratory are relied upon to remove the finest particles suspended in fluids, or just as a given chemical reagent is entrusted to remove

completely certain metals from a solution of their salts. It may be urged, however, that in spite of the severity of the tests which may have been organised in the laboratory, yet certain conditions might still obtain in practice which might lay bare a weak spot in its armour. This is not likely in view of the care that in certain recent researches has been given to include every possible source and kind of contamination which a water may undergo and with which the filter may have to deal. The researches of Dr. Kirchner, described in detail in the *Zeitschrift für Hygiene*¹ in 1893, and more recently of Dr. H. H. Johnston, published in a thesis prepared for the D.Sc. degree of Edinburgh University on the relative efficiency of certain filters for removing micro-organisms from water, afford, we think, most conclusive evidence in this respect. The experiments of the former were either in part or entirely made with more or less dilute broth and without pressure, the liquid being thus constantly of a high nutrient capacity for organisms and containing a multiplicity of them. The latter investigation extended from October, 1893, to June, 1894, and involved over 300 examinations of filtrates, some derived from ordinary main water and some artificially contaminated. The experiments with the tube filters extended over periods of from three to six weeks of continuous filtration, and showed that the Pasteur filter retained the organisms both in the main water and in other fluids in which organisms were contained, yielding an entirely sterile filtrate during the whole of the period. These results are valuable enough by themselves, but it is still more satisfactory to find that the purifying efficiency of the Pasteur-Chamberland tube is also attested by actual practical experience. Although the Pasteur filter has been hitherto little employed in this country, it has been very extensively used in France, and the effect of its adoption on the health of large bodies of men in sufficient numbers and under a sufficient variety of circumstances to exclude the effect of coincidence has been very carefully observed. The figures, for instance, relating to the French Army, and disclosed in recent reports of the Minister of War, which were based on the use of the Pasteur filter by some hundreds of thousands of men, together with the more special figures relating to cholera and dysentery in the army of occupation of Cochin China and the Dahomey expedition, leave very little doubt that the use of the Pasteur filter in practice is a real preventive of water-borne disease. In the light of results like these there can be no excuse for reminding the profession of the existence of such a valuable instrument for good. There are, however, one or two points which have recently occurred to us in connexion with the working and construction of this filter which deserve to be more widely known and understood than it seems to us they appear to be. There is, for example, the impression, which has not unreasonably gained ground, that the material of which the filter tube is composed is so dense as to resist the passage of water through it unless considerable pressure is applied. As a matter of fact, this is not so, judging from recent experiments we have made with a domestic filter which has recently been submitted to us by Messrs. Defries and Sons of 147, Houndsditch, E.C. This filter, which was of two gallons capacity, contained three small Pasteur tubes, connected with a piece of rubber tubing outside, extending a short distance below the bottom of the filter. When the filter is filled the water gradually percolates through the walls of the tubes and finally overflows through the rubber tube, the rate of filtration depending, of course, upon the depth of fall of the delivery tube, or, in other words, upon the length of the longer limb of what really constitutes a syphon. By placing the filter high up upon a shelf, and thereby increasing the length of the outside limb considerably, the delivery of filtered water is quite rapid, but even with a short length of eighteen inches the water is delivered at a rate sufficient for all ordinary drinking purposes. In one test the flow of filtered water was found to be equal to two pints and a half per hour, which may be reckoned as equal to an output of three gallons per day. Another apparent drawback to the Pasteur filter is its incapacity to deal with the objectionable taste or smell that may chance to characterise some waters. When, however, regard is had to the fact that the Pasteur tube is simply and solely a perfect strainer, being, it should be added, of such interstitial structure as to effectually remove organisms, this is not surprising—it will not remove, that is to say, gases or solids existing in true solution, since it exerts a strictly mechanical and not a chemical effect upon

the organic impurities contained in the water. Where, however, there is an unpleasant taste or smell or an objectionable material in the composition of the water to be filtered a supplementary addition is made to the Pasteur filter for the purpose of removing it. This consists in the use of some well-known oxidising material. In most waters intended for domestic drinking, however (as, for example, the London supplies), such an auxiliary is seldom required. Instinctively we avoid water that is offensive to the senses; but the Pasteur filter comes to our aid in effectually warding off more insidious dangers, which under ordinary circumstances our senses fail to perceive.

Obituary.

KENNETH CORBET, M.D. ABERD., L.F.P.S. GLASG., L.M.

DR. CORBET, of Beaulieu, Inverness-shire, whose death occurred on the 16th inst., not unexpectedly, for he had, we are informed, been in failing health for several months, will be greatly missed in his neighbourhood, where he was very popular and had an extensive practice. Apart from his professional attainments he was a man of much culture, well versed in Highland folk-lore and in local history and genealogy. Beaulieu being his native place, he was naturally a proficient in the Gaelic language and literature. His first start in life was as an apprentice to a firm of pharmaceutical chemists in Inverness. He subsequently proceeded to Glasgow, where he studied medicine at the University, and in 1854 graduated as M.D. at Aberdeen. Dr. Corbet was appointed surgeon to the local Volunteer force almost on its first formation. He was conspicuous among the early promoters of the movement, and retained his appointment until only a few years ago, retiring with the rank of lieutenant-colonel. He communicated to our columns the results of more than one interesting observation.

JOHN ABERNETHY HICKS, L.F.P.S. AND L.M. GLASG., L.S.A. LOND.

The death is announced, on Jan. 17th, at the age of fifty-eight years, at Bexhill-on-Sea, Sussex, of Mr. John Abernethy Hicks after a lingering illness. He was the second son of the late John Hicks, surgeon (a pupil of Abernethy), of Emsworth, Hants, whose family have been medical practitioners in that neighbourhood for over 150 years. Having chosen the medical profession he was apprenticed to Dr. Walter Raleigh Baxter of Emsworth, who had succeeded his father, lately deceased. In due course he entered jointly at the Westminster Hospital and the Grosvenor-place School of Medicine. Soon after the commencement of the Crimean War he obtained a commission as Acting Assistant Surgeon; he served throughout the campaign till peace was declared, and was awarded the English and Turkish medals. After that he resumed his medical studies in London, and in 1862 obtained the diploma of L.S.A. and in 1865 the L.F.P.S. and L.M. of Glasgow. He married in 1866 the only daughter of the late Charles Davenport, surgeon, of Abbridge and Chigwell-row, Essex, whose practice he succeeded to and carried on for some years. He leaves a widow, one daughter, and three sons. One of the sons, Mr. Jno. Abernethy Hicks, is in the medical profession.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Külz, distinguished for his researches in physiological and pathological chemistry. He was born in 1845, and in 1880 became Professor of Physiology in the University of Marburg, where he has just died. He contributed much to our knowledge of diabetes, so that, although he was not a practising physician, his advice was sought by diabetic patients from all parts of the world. The University students found him a very strict examiner; some years ago they refused to attend his lectures, and the Minister of Public Instruction was compelled to interfere. In the early part of his medical career he was assistant to Professor Mannkopf. His special studies, both clinical and physiological, have been connected with diabetes,

¹ Vol. xiv., p. 299, and vol. xv., p. 179 et seq.

and in 1879 he was appointed to the chair of Physiology in succession to Dr. Nasse. It is an open secret that he had for some time past been the private adviser of the Prussian Education Department in medical matters.—Dr. Gottstein, the celebrated Professor of Laryngology in Breslau. He was born in Lissa (Posen) in 1832. He took a leading position among the early laryngoscopists and became well known for his performance of endo-laryngeal operations. He afterwards cultivated otology and made valuable researches into the structure of the cochlea. His works included a useful text-book on Diseases of the Throat, which has been translated into several languages.—Dr. Poppelauer, a Berlin Privy Councillor, and one of the senior members of the medical profession in that capital.—We regret to see that a *Kenter* telegram announces the death of Dr. Loomis of New York as having occurred at that city on Wednesday last.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board in the subjects indicated at a meeting of the Examiners on Thursday, Jan. 10th:—

Anatomy and Physiology:

Atal, Pundit Prady Lal, Punjab University, Lahore.
Caglieri, Guido Enrico, California University and University College, London.
Dhingre, Behari Lal, Punjab University, Lahore.
Douglas, Percy Clarence, St. Mary's Hospital.
Grapel, Francis Gaspar, University College, London.
Harris, Norman MacLeod, Toronto University, Canada.
Hine, Hugh FitzNeville, Middlesex Hospital.
Lincoln, Charles Hope Septimus, Guy's Hospital.
Robertson, Richard Connon, Charing-cross Hospital.
Wilkinson, Arthur Wilfred, St. Bartholomew's Hospital.

Anatomy only:

Andrews, Cecil Edward, London Hospital.
Hay-Coghlan, William Killeagh, St. Mary's Hospital.
Lewis, Lionel Hugh, Guy's Hospital and University College, Cardiff.
Pattison, Albert John, London Hospital.
Robinson, John Hugh Ripon, London Hospital.
Miles, William, St. Mary's Hospital and University College, Cardiff.
Miller, George Valentine, University College, London.

Physiology only:

Amsden, Walter, St. Bartholomew's Hospital.
Foster, George Muir, University College, London.
Gibson, Charles Walter, Guy's Hospital.
Grucly, Edgar John, London Hospital.
Hendley, Albert Richard, Middlesex Hospital and Mr. Cooke's School of Anatomy and Physiology.
St. John, Winstan St. Andrew, St. Mary's Hospital.
Waller, Harry Mortlock, St. Bartholomew's Hospital.

Fifteen gentlemen were referred in both subjects, six in anatomy only, and seven in physiology only.

The following gentlemen passed the First Examination of the Board, in the subjects indicated, at the quarterly meeting of the Examiners, under the five years' regulations:—

Part I., Chemistry and Physics:

Alltree, George William, King's College, London.
Bayly, Francis Stephen Goodenough, St. Thomas's Hospital.
Bent, Vincent Thomas Clare, Guy's Hospital.
Bingham, Frank Miller, St. Thomas's Hospital.
Blackstone, Charles Edgar, Middlesex Hospital.
Boyle, William Francis, Charing-cross Hospital.
Browne, Edward Wemyss, St. Thomas's Hospital.
Bullen, Edward Harry, St. Mary's Hospital.
Churton, John Gaitzkell, University College, Liverpool.
Cooper, Walter Edward, University College, London.
Corbett, Sidney D'Alton, St. George's Hospital.
Cox, William Alfred Clayton, St. Mary's Hospital.
Crawford, Vincent James, Guy's Hospital.
Crawley, Herbert Edward, Oxford University.
Davies, Walter C. C. Cornwalleys, St. Mary's Hospital.
De Coteau, Joseph Taph., Guy's Hospital.
De Freitas, Quirino Bonifacio, King's College, London.
Drake-Brockman, Ralph Evelyn, St. George's Hospital.
Driver, Henry Lloyd, St. George's Hospital.
Eastment, Gerald Meade, Middlesex Hospital.
Evans, Arthur Robert, University College, Cardiff.
Faulkner, Erasmus Oakes, St. Mary's Hospital.
Fawley, Tom Bower, Yorkshire College, Leeds.
Featherstone, Frank Reginald, Guy's Hospital.
Glaze, Thomas Horace, Mason College, Birmingham.
Gowing, Benjamin, Yorkshire College, Leeds, and Firth College, Sheffield.
Grindle, Cyril Page, St. Mary's Hospital.
Hand, Frederick Harold, St. George's Hospital.
Horton, Horatio Nelson, Middlesex Hospital.
Hudson, Edmund, Owens College, Manchester.
Hughes, Norman Alexander Aylmer, Yorkshire College, Leeds.

Illius, John Warwick, St. Bartholomew's Hospital.
Langdon, Harold Steele, Middlesex Hospital.
Lees, Charlie, Charing-cross Hospital.
Macintosh, Archibald Malcolm, St. Mary's Hospital.
Merry, Edward, London Hospital.
Michell, Ralph, Guy's Hospital.
Morley, Arthur Solomon, St. George's Hospital.
Moss-Blundell, Cuthbert Blundell, St. Thomas's Hospital.
Newton, Courtenay Howard, St. Thomas's Hospital.
Newton, Reginald Goldie, Oxford University.
Oxley, James Charles Stewart, St. Thomas's Hospital.
Parker, Herbert Alban, St. Thomas's Hospital.
Patch, Burnet Graham, St. Thomas's Hospital.
Pern, Norman, St. Thomas's Hospital.
Phillips, Norman Routh, London Hospital.
Pritchard, Sydney Clifford, King's College, London.
Rohil, Juan Jose, Guy's Hospital.
Row, Charles Martin, University College, London.
Row, Edward Reginald, Guy's Hospital.
Rutherford, William Harper, St. Thomas's Hospital.
Smith, Alan Ayre, Guy's Hospital.
Smith, Hugh, Mason College, Birmingham.
Sturdy, Harry Carlile, Guy's Hospital.
Tatchell, Percy, St. Bartholomew's Hospital.
Tredgold, Alfred Frank, London Hospital.
Vaughan, Arthur Llewellyn, St. Bartholomew's Hospital.
Vosper, Percy, King's College, London.
Weston, Alfred Follam, St. George's Hospital.
William, Norman, Otago University and Guy's Hospital.

Part II., Practical Pharmacy:

Brown, Alexander, King's College, London.
Horsburgh, Charles Bethune, University College, Bristol.
Humbly, Harry Robinson, St. Bartholomew's Hospital.
McMullen, William Halliburton, King's College, London.
Mason, Samuel, St. Bartholomew's Hospital.
Page, Shirley, Mason College, Birmingham.
Reid, Allen George, London Hospital.
Sass, Frederick Joseph Wilfred, St. Mary's Hospital.
Simpson, Graham Seales, Guy's Hospital.
Sprawson, Cuthbert Allan, King's College, London.
Storrs, Reginald, St. Bartholomew's Hospital.
Tatchell, Percy, St. Bartholomew's Hospital.
Tredgold, Alfred Frank, London Hospital.
Unsworth, Noel, St. Thomas's Hospital.
Whitaker, Leonard Edgar, St. Bartholomew's Hospital.

Part III., Elementary Biology:

Agar, William Harold, University College, London.
Agate, Henry St. Arnaud, St. Mary's Hospital.
Ainscow, James, Owens College, Manchester.
Anley, Frederick Eustace, Charing-cross Hospital.
Austin, Alfred Chalmers, St. Mary's Hospital.
Barlet, Jehan Meredith, St. Mary's Hospital.
Batchelor, Henry Charles, Guy's Hospital.
Beasley, Joseph Howard, Mason College, Birmingham.
Brind, Alfred Michael, Mason College, Birmingham.
Bullen, Edward, St. Mary's Hospital.
Carr, Henry Brookes, Guy's Hospital.
Chapman, Donald Poyntz, Charing-cross Hospital.
Coleman, Frank, Charing-cross Hospital.
Cox, William Alfred Clayton, St. Mary's Hospital and School of Science, Cheltenham.
Dalziel, Arthur Montgomerie, St. Bartholomew's Hospital.
Davies, Frank Aaron, Mason College, Birmingham.
Dewick, George, St. Thomas's Hospital.
Double, Meredith Sedgwick, Charing-cross Hospital.
Driscoll, Louis Cornelius, Charing-cross Hospital.
Feddén, Walter Fedde, St. Paul's School, London.
Garne, Sydney William, Charing-cross Hospital.
Goodwin, William Richard Power, St. Mary's Hospital.
Gribbell, William Ernest, St. Mary's Hospital.
Hipwell, Harry, Middlesex Hospital.
Humphreys, Jack Edmund, Charing-cross Hospital.
Jones, Ernest Samuel, University College, Cardiff.
Kilpatrick, James Armstrong, University College, Cardiff.
Kirkcounel, Edward Birchall, Owens College, Manchester.
Kirkman, Albert Henry Beaumont, Guy's Hospital.
Lamborn, William Alfred, Middlesex Hospital.
Lees, Charles, Charing-cross Hospital.
Lister-Kaye, Allan, Guy's Hospital.
Lloyd, Hugh Edward Drummond, St. Bartholomew's Hospital.
McIntyre, Daniel, Owens College, Manchester.
Martin, Malcolm Munro, St. Bartholomew's Hospital.
Maynard, George Darell, St. Mary's Hospital.
Newport, Alexander Charles, Charing-cross Hospital.
Passmore, William Henry, Charing-cross Hospital.
Pinches, Henry Irving, St. Paul's School, London.
Rhodes, Thomas Basil, Mason College, Birmingham.
Roche, Ivan Joseph, Charing-cross Hospital.
Rockwood, David Pratt, University College, London.
Row, Charles Martin, University College, London.
Scott, Henry Martin, Charing-cross Hospital.
Simpson, John Edgar, University College, London.
Smith, Percy Nelson, St. Mary's Hospital.
Smith, Sydney Joseph, Charing-cross Hospital.
Southan, Percy, Mason College, Birmingham.
Speirs, George Benjamin Armes, St. Mary's Hospital.
Sprague, Francis Henry, St. Mary's Hospital.
Stone, Gerald William, St. Bartholomew's Hospital.
Tayler, Henry Christopher, St. Mary's Hospital.
Thompson, William Atkin, Owens College, Manchester.
Tonge, George Preston, St. Paul's School, London.
Vawdrey, Percy Llewellyn, St. Bartholomew's Hospital.
Von Rosen, Alfred Dittlof Benedictus, St. Mary's Hospital.
Wagstaff, Charles Bertrand, Charing-cross Hospital.
Wells, Hardy Vesey, St. Mary's Hospital.
Westlake, Bernad Beaumont, Guy's Hospital.

Weston, Alfred Fullam, St. George's Hospital.
Whitaker, Leonard Edgar, St. Bartholomew's Hospital.
Wilshaw, Thomas Hatcliffe, Mason College, Birmingham.
Woodcock, Henry Chadwick, St. Mary's Hospital.

Part IV., Elementary Anatomy :

Alderson, Francis Bellairs, Firth College, Sheffield.
Barnes, Ernest Charles, London Hospital.
Bathurst, William Henry Isaac, King's College, London.
Bradley, John Bird, Mason College, Birmingham.
Bridger, James Frederick Edmund, St. Mary's Hospital.
Clogg, Herbert Sherwell, University College, Cardiff.
Cocke, Robert Sturgeon, King's College, London.
Davies, Frank Aaron, Mason College, Birmingham.
Dowsett, Ernest Blair, Guy's Hospital.
Francis, William Vane Chalmers, Westminster Hospital.
Garne, Sydney William, Charing-cross Hospital.
Gowing, Benjamin, Firth College, Sheffield, and Yorkshire College, Leeds.
Hamilton, William Gairn, St. Bartholomew's Hospital.
Herklots, Gerard Andreas, University College, London.
Hogan, Roger Joseph, London Hospital.
Hope, Walter Bayard, Guy's Hospital.
Humphreys, Jack Edmund, Charing-cross Hospital.
Jones, Ernest Samuel, University College, Cardiff.
Jones, John, University College, London, and Mr. Cooke's School of Anatomy and Physiology.
Joy, Norman Humbert, St. Bartholomew's Hospital.
Kelly, Thomas Thelwell, Guy's Hospital.
McClintock, John, King's College, London.
McIntyre, Daniel, Owens College, Manchester.
McLachlan, Arthur Ronald, Guy's Hospital.
Martin, Malcolm Murett, St. Bartholomew's Hospital.
Maynard, George Darell, St. Mary's Hospital.
Moggridge, Charles Francis Blagney, St. Thomas's Hospital.
Oliver, Arthur Cardell, University College, Cardiff.
Phillips, Norman Routh, London Hospital.
Reid, Allan George, London Hospital.
Ricketts, Arthur, University College, London.
Ruttledge, William Edward, University College, London.
Scott, Aleck Lauriston, St. Bartholomew's Hospital.
Smith, Sydney Joseph, Charing-cross Hospital.
Smith, Thomas William, Charing-cross Hospital.
Stone, Gerald William, St. Bartholomew's Hospital.
Stuart, Hackworth, University College, London.
Thomas, Alfred Messer, Guy's Hospital and Durham University.
Thomas, David Jones, London Hospital.
Unsworth, Noel, St. Thomas's Hospital.
Unwin, William Howard, Charing-cross Hospital.
Walker, John Frederick, London Hospital.
Wagstaff, Charles Bertrand, Charing-cross Hospital.
Wilshaw, Thomas Hatcliffe, Mason College, Birmingham.
Yoxall, Edward, Mason College, Birmingham.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates have passed in the under-mentioned subjects :—

Surgery.—R. B. Allen, St. Mary's Hospital; C. M. Beadnell, Guy's Hospital; W. S. Dibbs, Leeds; A. Douglas, Birmingham; R. H. Hayes, Guy's Hospital; P. S. Kesteven, St. Bartholomew's Hospital; W. A. Montgomery, St. Thomas's Hospital; A. T. Petyt, Leeds; E. P. Staples, St. Mary's Hospital; T. Stevens, Charing-cross Hospital; C. S. Taylor, Manchester; and J. M. Troup, King's College.

Medicine, Forensic Medicine, and Midwifery.—H. W. Clarke, St. Mary's Hospital; T. S. Collin, Manchester; L. C. Dillon, King's College; W. MacLellan, St. Mary's Hospital; G. P. U. Prior, King's College; and J. H. Whitaker, Belfast.

Medicine and Forensic Medicine.—O. W. Gange, University College.

Medicine and Midwifery.—A. H. Trevor, Guy's Hospital.

Medicine.—M. T. Archdall, Charing-cross Hospital; and T. Watts, Manchester.

Forensic Medicine.—T. Morris, Liverpool.

Midwifery.—W. J. H. Dawson, St. Thomas's Hospital; and P. S. Kesteven, St. Bartholomew's Hospital.

To Messrs. Allen, Archdall, Clarke, Dillon, Douglas, Hayes, MacLellan, Morris, Prior, and Stevens was granted the diploma of the society.

FOREIGN UNIVERSITY INTELLIGENCE.—*Amsterdam*: Dr. M. Straub has been appointed Extraordinary Professor of Ophthalmology.—*Berlin*: Dr. O. Heubner has been appointed to the newly established Professorship of Children's Diseases.—*Constantinople (Military Medical School)*: Dr. Rifat Bey has been appointed Professor of Pathological Anatomy in succession to the late Dr. Ohanes Bey.—*Leipsic*: Dr. Friedrich has been recognised as *privat-docent* in Surgery.—*New York (Post-graduate School)*: Dr. R. Guiteras has been appointed Professor of Operative Surgery.—*St. Petersburg (Military Medico-Chirurgical Academy)*: Dr. J. A. Praxin has been recognised as *privat-docent* in Surgery.

A SESSIONAL MEETING of the Sanitary Institute will be held at the Parkes Museum on Wednesday, Feb. 13th, at 8 P.M., when a discussion will be opened by Dr. George Vivian Poore, F.R.C.P., on Dry Methods of Sanitation. The chair will be taken by Sir Thomas Crawford, K.C.B.

OFFICIAL RECEPTION BY THE SHERIFF OF YORK.—On the 16th inst. the Sheriff of the city of York (Dr. Tempest Anderson, J.P.) held an official reception in the York Exhibition Buildings. About 2000 guests attended and spent a most enjoyable evening. Dr. Anderson delivered an elaborate and important address on Man and his Habitation, illustrated by a series of lantern slides showing the development of human habitations from cave dwellings. Many objects of great scientific interest were on view, including a phonograph and a double pendulum apparatus for drawing harmonic curves.

THE board of governors of the Suffolk General Hospital at Bury St. Edmunds have regretfully accepted the resignation of Dr. Robert Macnab, the senior medical officer of the hospital, who has been on the medical staff of the institution for nearly thirty years. At a special meeting of the governors it was reported that Dr. Macnab could not be induced to reconsider his decision, and the resignation was, therefore, formally accepted. Many speakers made most complimentary references to the past services of Dr. Macnab, who was unanimously appointed consulting medical officer.

WE have received the sixth annual report (1894) of the Scottish Branch of Queen Victoria's Jubilee Institute for Nurses. The object of this association is to provide trained nurses for the sick poor in their own homes. Her Majesty the Queen has been pleased to appoint H.R.H. the Princess Louise, Marchioness of Lorne, President of the branch for three years from Jan. 1st, 1894. Seventy-eight of these nurses are at work in different parts of Scotland, both urban and rural. Eight new local associations have been formed and have been affiliated to the institute. The ordinary expenditure has exceeded the receipts by £462, and the deficiency has been met out of a reserve fund.

PRESENTATIONS.—Mr. G. E. Helme, M.B., C.M. Edin., on the occasion of his resigning the position of house surgeon at the district hospital, West Bromwich, was the recipient from past and present in-patients of that institution of a handsome case containing a set of surgical instruments in testimony of their respect and esteem.—Mr. W. J. C. Keats, L.R.C.P. Lond., M.R.C.S., has been presented with a cake basket by the nurses of the Greenwich Union Workhouse "as a token of their appreciation of the benefits derived by them from attending a course of his lectures at the infirmary."—Mr. M. R. Rich, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., of Crowland, Lincolnshire, has been presented with the Royal Humane Society's medal for saving a lad from drowning in November last.

INFIRMARY NURSING.—A meeting convened by the Matrons' Council, and held at the rooms of the Medical Society of London on the 17th inst., was largely attended by hospital and infirmary matrons, by medical men, and by Poor-law guardians. The chair was taken by Dr. Bedford Fenwick, and a paper was read by Miss Mollett, matron of the South Hants County Hospital and late matron of the Chelsea Infirmary, upon the Conditions of Nursing under the Poor-law. The lecturer drew special attention to the importance of delimiting and defining the respective duties of the medical superintendent and the matron of the workhouse infirmaries, showing that many of the disputes and nearly all the friction now so frequent are due to the present system.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Lectures will be delivered at the College during the winter session by Mr. W. G. Spencer, F.R.C.S. (Aris and Gale Lecturer), on "The Central Nervous Mechanism of Respiration," on the 18th, 20th and 22nd of February; Professor C. B. Lockwood, on "Traumatic Infection," on the 25th and 27th of February and the 1st of March; Professor Charles Stewart, on "A Revision of the Endoskeleton in the Physiological Series in the Museum of the College," on the 11th, 13th, 15th, 18th, 20th and 22nd of March; Professor Joseph Griffiths, on "The Testis," on the 25th, 27th and 29th of March; and Mr. J. H. Targett, F.R.C.S. (Erasmus Wilson Lecturer), on "Recent Additions to the Museum of the College," on the 1st, 3rd and 5th of April.

THE Musical Society of Middlesex Hospital gave their last periodical concert in the board room of the hospital on Thursday, Jan. 24th, at 5.30 P.M.

THE Congress of the British Institute of Public Health will be held this year in Hull, upon the invitation of the Mayor, the Sheriffs, and Town Councillors of that borough.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information available for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

BAILEY, W. H., M.B. Lond., M.R.C.S., D.P.H., has been appointed Medical Officer for the East Dulwich Sanitary District of the parish of St. Giles, Camberwell.

BARR, JAMES, M.D. Glasg., L.R.C.S., L.M. Edin., has been reappointed Physician to the Liverpool Northern Hospital.

BARROW, V. E., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Sampford Peverell Sanitary District of the Tiverton Union.

BATTEN, FREDERICK E., M.D. Cantab., M.R.C.P. Lond., has been appointed Assistant Physician to the Hospital for Sick Children, Great Ormond-street.

BROOKSHANK, H. J., B.A. Cantab., has been appointed House Surgeon to the Victoria Hospital for Children.

CAMPBELL, W. M., M.D. Edin., M.R.C.S. Eng., has been reappointed Consulting Surgeon to the Liverpool Northern Hospital.

COLMER, P. A., L.R.C.P. Lond., M.R.C.S., has been reappointed Honorary Surgeon to the Yeovil District Hospital and Dispensary.

DICKINSON, E. H., M.D. Edin., F.R.C.P. Lond., L.R.C.P., L.R.C.S. Edin., has been reappointed Physician to the Liverpool Northern Hospital.

ELAM, GEORGE, M.D. Durh., B.S., M.R.C.S., L.R.C.P., has been appointed Honorary Surgeon to the Invalid Asylum, Stoke Newington.

HARRISON, D., F.R.C.S. Edin., M.R.C.P., L.M. Irel., M.R.C.S. Eng., has been reappointed Honorary Surgeon to the Liverpool Northern Hospital.

HUNT, M. A., L.R.C.P. Lond., M.R.C.S., has been reappointed Honorary Dental Surgeon to the Yeovil District Hospital.

HESTER, W. L., M.D., B.Ch. Dubl., D.P.H. Eng., has been appointed Medical Officer of Health for the Putney District Council.

JACOB, E. L., M.R.C.S., has been appointed Medical Officer to the Leatherhead Urban Council.

JAMES, C. A., M.R.C.S., L.R.C.P. Lond., D.P.H., has been appointed Consulting Surgeon to the Invalid Asylum, Stoke Newington.

LAWFORD, J. B., F.R.C.S. Eng., has been appointed Ophthalmic Surgeon to St. Thomas's Hospital, London.

MAHOOD, A. E., M.B., M.Ch. Irel., F.R.C.S. Eng., has been reappointed Medical Officer for the Northam Sanitary District of the Biddeford Union.

MANIFOLD, W. H., M.R.C.S., has been reappointed Consulting Surgeon to the Liverpool Northern Hospital.

MARSIE, C. J., L.R.C.P., L.M. Edin., M.R.C.S., has been reappointed Honorary Surgeon to the Yeovil District Hospital and Dispensary.

MATTHEWS, WM., L.D.S.R.C.S. Eng., has been reappointed Dental Surgeon to the Liverpool Northern Hospital.

McMATH, WM., M.B., B.Ch. Irel., has been appointed Medical Officer to the Queen-street Friendly Benefit Society, Cork.

MONTGOMERIE, H. M., M.D., C.M. Edin., has been reappointed Physician to the West Cornwall Infirmary and Dispensary.

MONTGOMERY, J. B., M.D. Glasg., F.R.C.P. Lond., L.R.C.S. Edin., M.R.C.S., has been reappointed Consulting Physician to the West Cornwall Infirmary and Dispensary.

OLIPHANT, FRANK, M.B. Edin., has been appointed Junior House Surgeon to the Chesterfield Hospital.

PEARCE, A. CHANING, M.B. Lond., has been appointed House Physician to the Victoria Hospital for Children.

PUZEY, C., F.R.C.S., L.M., L.R.C.P. Lond., has been reappointed Honorary Surgeon to the Liverpool Northern Hospital.

SYMONS, J., M.R.C.S., has been reappointed Surgeon to the West Cornwall Infirmary and Dispensary.

WALKER, G. E., F.R.C.S. Eng., M., has been reappointed Consulting Ophthalmic Surgeon to the Liverpool Northern Hospital.

WALKER, H. S., F.R.C.S., has been appointed Lecturer on Ophthalmology and Otolaryngology at the Yorkshire College, Leeds.

WILSON, A. H., L.R.C.P. Lond., M.R.C.S., has been reappointed Honorary Surgeon to the Liverpool Northern Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

CANCER HOSPITAL (Free), Fulham-road, S.W.—House Surgeon for six months. Salary at the rate of £50 per annum, with board and residence.

CENTRAL LONDON OPHTHALMIC HOSPITAL, 238A, Gray's-inn-road, W.C.—House Surgeon. Rooms, coals, and light provided.

DEWSBURY AND DISTRICT INFIRMARY, Dewsbury.—House Surgeon. Salary £80, with board and residence.

GENERAL HOSPITAL FOR SICK CHILDREN, Pendlebury, Manchester.—Junior Resident Medical Officer, for one year. Salary £80 per annum, with board and lodging.

HOSPITAL FOR DISEASES OF THE THROAT, Golden-square, London, W.—Clinical Assistants. Also Registrar and Pathologist for six months. An honorarium at the rate of 25 guineas a year.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Shoreditch, N.E.—Junior House Physician for six months. Board and lodging (including washing) provided.

ROYAL SOUTH LONDON DISPENSARY.—Surgeon in Ordinary to visit patients at their own homes in the Waterloo District. Honorarium £20 per annum. Applications at the Dispensary, St. George's-cross, S.E.

SALFORD ROYAL HOSPITAL.—House Surgeon. Salary £100 per annum, with board and residence.

SALOP INFIRMARY, Shrewsbury.—House Surgeon. Salary £100 per annum, with board and residence.

STAFFORDSHIRE GENERAL INFIRMARY, Stafford.—House Surgeon for two years. Salary £100 per annum, with board, lodging and washing.

TACANTON AND SOMERSET HOSPITAL, Taunton.—Honorary Surgeon.

Births, Marriages, and Deaths.

BIRTHS.

DUFF.—On Jan. 22th, at Tyrwhitt-road, St. John's, S.E., the wife of C. E. Duff, M.B., of a son.

ELAM.—On Jan. 17th, at Manor-road, Stoke Newington, N., the wife of George Elam, M.D., of a son.

FLETCHER.—On Jan. 22th, at Harley-street, the wife of H. Morley Fletcher, M.D., of a daughter.

GILBERTSON.—On Jan. 13th, at Hitchin, the wife of James Henry Gilbertson, L.R.C.P. Lond., M.R.C.S., of a daughter.

GREEN.—On Jan. 14th, at Rutherglen, Woodside, the wife of E. F. S. Green, M.D., of a son.

HAMLEN-WILLIAMS.—On Jan. 20th, at Belgrave-mansions, Grosvenor-gardens, S.W., the wife of T. R. Hamlen-Williams, M.R.C.S., L.R.C.P., Fairfield, Pontypool, Glam., of a daughter.

MORTON-WILSON.—On Jan. 18th, at Carlton-villas, Chichele-road, Cricklewood, N.W., the wife of G. Morton-Wilson, M.B., of a daughter.

SLAUGHTER.—On Jan. 18th, at A-hampton-road, Southsea, the wife of Surgeon-Lieutenant-Colonel W. B. Slaughter, A.M.S., of a son.

SUMPTER.—On Jan. 8th, at 2, Harley-place, W., the wife of W. J. Ernely Sumpter, M.R.C.S. Eng., and L.R.C.P. Lond., &c., of Sheringham, Norfolk, of a son.

SWAYNE.—On Jan. 16th, at Leicester-place, St. Paul's-road, Clifton, the wife of Walter C. Swayne, M.D., of a daughter.

SYLVESTER.—On Jan. 18th, at Trowbridge, Wiltshire, the wife of Kirwan F. Sylvester, Surgeon, of a daughter.

WARNER.—On Jan. 17th, at Brechin-place, S.W., the wife of F. Ashton Warner, F.R.C.S., of a son.

MARRIAGES.

CLARKE-ROBINSON.—On Jan. 7th, at Holy Trinity Church, Crockham-hill, Fielding Clarke, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A. Lond., to Jamie, second daughter of Joseph Robinson, Esq., of Lewins, Crockham-hill, Kent.

DUGGAN-MAUNDE.—On Jan. 14th, at Chetwynd Church, Newport, Salop, Surgeon-Captain C. W. Duggan, M.B., Army Medical Staff, to Crystal Maunde, youngest daughter of W. H. Maunde, Esq., of Merevale, Newport, Salop.

WARD-ROLFE.—On Jan. 9th, 1895, at Great Amwell, George Smith Ward, L.R.C.P., Stevenage, to Fanny Stock Rolfe, of Leigh Court, Amwell.

DEATHS.

FITCH.—On Jan. 12th, at Alma-square, Scarborough, Samuel Edward Fitch, M.D., Clerk in Holy Orders, aged 84.

GOODSIR.—On Jan. 17th, at 11, Danube-street, Edinburgh, Robert Anstruther Goodsir, M.D., aged 71 years.

HICKS.—On Jan. 17th, 1895, at Oakhurst, Bexhill-on-Sea, in his 58th year, John Abernethy Hicks, L.F.P.S. and L.M. Glasg., L.S.A. Lond., son of the late John Hicks, surgeon of Bmsworth, Hants, and son-in-law of the late Charles Davenport, surgeon of Abridge and Chigwell Row, Essex. Interred at Epping, Essex.

JACKSON.—On Jan. 16th, at Nice, Deputy-Surgeon-General C. J. J. Jackson, H.M. Indian Medical Service (retired), aged 64.

WHISHAW.—On Jan. 20th, at Mentone, Alpes Maritimes, Brigade-Surgeon J. C. Whishaw, Bengal Army (retired), aged 62.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopaedic (2 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Gt. Northern Central (2.30 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North West London (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).

(At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.)

SOCIETIES.

MONDAY.—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Percy Kidd: A successful case of Paracetamol Pericarditis.—Dr. E. Cautley: The Treatment of Empyema in Children, based on an Analysis of Eighty-six Cases.

THURSDAY.—OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8 P.M. Card Specimens:—Messrs. Hodge and Ridley: Intracocular Melanotic Sarcoma with Peculiar Characteristics.—Mr. Lawford: Unusual Arrangement of the Retinal Vessels.—Dr. Argyll Robertson: Filariæ Lœa.—Mr. Marcus Gunn: (1) Peculiar Lenticular Changes following Old Injury of Eyeball; (2) Prolonged Hyperæmic Congestion of Optic Discs closely simulating Papillitis. 8.30 P.M. Papers:—M. Darier: Subconjunctival Injections of Mercury.—Mr. Jessop: Two cases of Diphtheritic Ophthalmia treated by Klein's Antitoxin.—Mr. Wray: Removal of the Lens for High Myopia with a case of —25 D.—Dr. G. Ogilvie: A case of Double Optic Atrophy with Peculiar Visual Fields.—Dr. G. Mackay: Eyesight and the Public Services.

FRIDAY.—WEST KENT MEDICO-CHIRURGICAL SOCIETY (Miller Hospital, Greenwich).—8.15 P.M. Dr. Morgan Dockrell: Cutaneous Syphilis. WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8.30 P.M. Mr. C. Bucknell: A Case of Cowpox in Man.—Mr. Keetley: On Intestinal Affections requiring Surgical Treatment. Card Specimens by Messrs. Bidwell and Keetley and Dr. Abraham.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY.—SOCIETY OF ARTS.—3 P.M. Prof. Silvanus P. Thompson: The Arc Light. (Cantor Lecture.)

TUESDAY.—ROYAL INSTITUTION.—3 P.M. Prof. Charles Stewart: The Internal Framework of Plants and Animals. (III.) CENTRAL LONDON THROAT AND EAR HOSPITAL.—4.30 P.M. Dr. Lennox Browne: The Antitoxin Treatment.

WEDNESDAY.—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 P.M. Lecture by Dr. Gowers. ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-sq., W.C.).—5 P.M. Dr. Morgan Dockrell: Diseases of Nails. WEST LONDON HOSPITAL (Hammersmith-rd., W.).—5 P.M. Dr. Seymour-Taylor: Cases of Thoracic Aneurysm. (Post-graduate Course.) SOCIETY OF ARTS.—3 P.M. Mr. Thomas Child: Peking.

THURSDAY.—ROYAL INSTITUTION.—3 P.M. Mr. W. S. Lilly: Four English Humourists of the Nineteenth Century. (III.) SOCIETY OF ARTS (Imperial Institute).—4.30 P.M. Sir Alexander Wilson (for Mr. S. E. J. Clarke of Calcutta): India and its Women.

FRIDAY.—ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-square, W.C.).—11 to 1 P.M. Dr. Barratt: The Pathology of the Skin. ROYAL INSTITUTION.—3 P.M. Mr. Henry Irving: Acting—An Art.

SATURDAY.—ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-square, W.C.).—11 to 1 P.M. Dr. Barratt: The Pathology of the Skin. 5 P.M. Dr. Morgan Dockrell: Tuberculosis of the Skin. ROYAL INSTITUTION.—3 P.M. Mr. Lewis F. Day: Stained Glass Windows and Painted Glass. (III.)

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used

MANAGER'S NOTICE

THE INDEX TO THE LANCET.

THE INDEX for the last half-year was published in our issue of Dec. 29th, which completed the second volume of the year 1894. Those of our subscribers who may wish to be supplied with loose copies can obtain the same (without extra charge) on making application to the Manager.

THE POST AS A MEDIUM OF REPRESSIBLE CIRCULARS.

A VALUED CORRESPONDENT sends us a circular received by one of his patients a few days after the announcement in the *Times* of the birth of a son. The burden of the circular was to urge the importance of circumcision as a duty to one's male progeny on all moral and physical grounds. The illiterate and ungrammatical composition of the circular does not atone for its audacity in its virtual reflection on Providence, or for the insult to respectable people in receiving such a document. We have before pointed out how the post becomes an agent for mischief in the hands of such persons. We would recommend any person receiving such documents to forward them to the Home Secretary and the Public Prosecutor for their consideration. Some remedy should be devised by these authorities for such uses of the post.

Westwood.—Our correspondent is strongly advised not to undergo the treatment to which he alludes.

CLUBS AND CHRONIC CASES.

To the Editors of THE LANCET.

SIRS,—Will some of your many readers give me the benefit of their opinion upon the following case—as to whether it should be termed "chronic"? A member of a lodge of Shepherds has received sick pay from the funds during the past five years upon seven different occasions on account of gout, for various periods, in all amounting to 168 working days out of a possible 1484. He has always, excepting on one occasion, when he returned to his work before he had regained his strength, in my opinion, been cured, and certified by me as able to follow his employment. There has been an absence of stiffness or alteration in structure or form of his joints and of any obvious impairment of the organs of circulation or digestion—the usual indications of chronic disease. He has been able to work satisfactorily between each attack, and from Oct. 14th, 1893, to Dec. 17th of last year he did not come upon the lodge at all. The secretary and other members of this the largest lodge of Shepherds in the district are disposed to view this case as one of chronic disease, taking as their text the "Dictionary of Medical and Surgical Knowledge," "chronic" being there described as "any disease of long standing, the opposite of acute, a term applied to all diseases which have passed their first or acute stage without being cured."

I am, Sirs, yours faithfully,

Jan. 11th, 1895.

PODAGRA.

AN INQUIRY.

To the Editors of THE LANCET.

SIRS,—Will you allow me to ask through THE LANCET for information concerning lyceol, which I am told is very beneficial in the treatment of gout, but about which I have not been able to obtain any particulars?

I am, Sirs, yours truly,

Falmouth, Jan. 17th, 1895.

ARTHUR B. HARRIS, M.D.

A TAPEWORM IN THE URETHRA.

DR. AXEL SPOOF, writing in *Duodecim*, a Finnish medical journal, mentions the case of a man who complained of pain in the region of the bladder, which whenever he sat down was also felt in the perineum—a trouble which he had had for several years. When Dr. Spoor saw him he was engaged in trying to draw a tapeworm from the urethra, the head having been the first portion to appear. All attempts at traction causing pain, it was decided to desist, and to introduce an opium suppository into the rectum. The next day the worm was easily removed and the patient was able to micturate freely, though he required to do so somewhat frequently. The urine was clear, but it contained a considerable number of white blood-corpuscles. No ova could be discovered. The patient was able to return to his home without delay.

Adenoid.—Our correspondent does not give us sufficient information to make it possible for us to reply. And with all the facts before us the proper fee for a particular surgeon to charge a particular patient for a particular operation is not a thing about which a definite decided opinion can always be given.

SULPHUR & ANTITOXIN IN THE TREATMENT OF DIPHTHERIA.

To the Editors of THE LANCET.

SIRS,—To my mind it seems extraordinary the way the medical profession rush, one might almost say blindly, after every new treatment. I should have thought that recent disappointments—the treatment of tuberculosis, for example—would have been a warning, and that caution would be the watchword. We see published in lay papers the wonderful properties of antitoxin, we hear of prominent men in the profession actually wanting subscriptions to found a laboratory for the manufacture of this almost untried antidote to diphtheria. Our old friend sulphur tells the diphtheritic to go and wash in Jordan and be clean. His advice is too simple; there is no display about it. The profession do not like it. Dr. Sumpter in your issue of Dec. 8th gives sulphur a testimonial to which antitoxin cannot hold a candle. Further, Dr. Mules in the same issue writes stating his disappointment in antitoxin. In these cases even one old friend turns up on the successful side. I can imagine the antitoxins saying, "Fancy condemning the treatment because it has failed in one or two cases," and yet we are constantly hearing the new remedy extolled from an experience of one case only. It has been remarked that sulphur has only a local action. I say such is not the case. Observe the silver worm by those who have taken sulphur for any time, and behold the result. Examine the sputum of a patient taking sulphur and the unbeliever must be convinced. As far as my own experience goes, and that of my professional brethren who have used sulphur in the proper way, the dread of diphtheria has almost disappeared. Sulphur can be used locally and constitutionally with the least possible inconvenience in either adult or infant. Swabbing the throat is objectionable in infants, especially as it frightens the child just at the time that all nervous shocks should be avoided. How is it proposed to give an infant a hypodermic injection without giving a severe nervous shock? I suggest that before going into ecstasy over a mere acquaintance we give our old friend an unbiased trial. The best statistics published give antitoxin, compared with sulphur, quite a secondary position. I ask that two hospitals be established where diphtheria is prevalent, and that every alternate case be admitted to the sulphur and antitoxin hospital for twelve months. If I were a betting man I would lay two to one on sulphur.—I am, Sirs, your faithfully,

Aberdovey, Dec. 11th, 1894. W. HAWKINS CUTHBERT, L.R.C.P. &c.

TREATMENT OF TAPEWORM.

To the Editors of THE LANCET.

SIRS,—Will any of your readers kindly tell me the best way of getting rid of tapeworm? I have prescribed pomegranate and male fern in drachm doses, given fasting, and though this readily expels the worm it always returns.

Jan. 21st, 1895.

I am, Sirs, yours faithfully,

A. M. S.

"CARAMELS."

To the Editors of THE LANCET.

SIRS,—Can any of my medical brethren tell me what caramels are? I was lately told by a lady that they were much used to improve the bust when the mammae were small or wasted. This is something new to me, and I was not able to say whether they were injurious or not.

Jan. 21st, 1895.

I am, Sirs, yours truly,

M.R.C.S. (Retired).

"POISONING BY NUTMEGS."

To the Editors of THE LANCET.

SIRS,—A reference to Section 366:3 of the "Medical Digest" would have enabled Mr. Simpson to learn that the case reported by him in the last issue of THE LANCET did not stand by itself, several other observers having reported similar symptoms after overdoses of nutmeg.

I am, Sirs, yours obediently,

Boundary-road, N.W., Jan. 19th, 1895.

B. NEALE, M.D. Lond.

THE EDISON-LALANDE GALVANO-CAUTERY.

To the Editors of THE LANCET.

SIRS,—Will any professional brother who has used the large-sized Edison-Lalande cells for minor galvano-cautery operations kindly give me the benefit of his experience? Do they work well and last well, and are they fairly constant?

Jan. 24th, 1895.

I am, Sirs, yours faithfully,

N.

THE VALIDITY OF BONDS IN CASE OF MEDICAL AID ASSOCIATIONS &c.

Specs.—Many of the medical officers of medical aid associations, feeling the galling nature of their work and position, would gladly escape from it. One of the modes of escape is the theory that contracts with a body of laymen for medical service are without force. This is not a sound position. It has been repeatedly negated in courts of law, which are notoriously strong in enforcing contracts. And ethically a bond is a bond and cannot be altered. The only course open to gentlemen so situated is to come to terms with their committee. Let those who are not so bound avoid such fetters.

"ON THE OCCURRENCE OF DIPHTHERITIC PARALYSIS WITHOUT PREVIOUS FAUCIAL AFFECTION."

To the Editors of THE LANCET.

SIRS,—On turning over the leaves of my last year's volumes of THE LANCET I was surprised to find that in the one for Nov. 3rd I had overlooked the above article by Dr. Leonard G. Guthrie. In it he summarises evidence found in a number of cases published by various writers relative to the paralytic sequelæ of diphtheria. Among them he quotes from a case of mine which appeared in the *Medical Times and Gazette* as far back as the year 1866, entitled "Case of Diphtheria by Inoculation appearing on a Wound without the Corresponding Affection of the Fauces, and followed by Paralysis." My principal motive in referring to this article is for the correction—if you will kindly permit it—of the orthographical mistake which Dr. Guthrie has made in the spelling of my name. My patronymic—"Paterson"—is spelled with only one t, but Dr. Guthrie doubles this letter which makes the name "Patter-son." In nine cases out of ten the person possessing the former name would be Scotch, and a like number called Paterson would be found to be English, so that the names are distinctive of the two countries. I find there are other slips, such as the year of publication. The case was published, as above stated, in 1866, but Dr. Guthrie writes in the footnote to his article 1868. Again, he gives the number of the paper 158 for the page 608, the correct indications being *Medical Times*, vol. ii., 1866, No. 658, p. 608, while his footnote reads *Medical Times*, vol. ii., 1868, p. 853. I am quite sensible these inaccuracies are trifling, but they are mistakes, and one, at least, if allowed to pass, might very easily in the future tend to mix matters, if not to raise a question as to the genuineness of my claim to the authorship of the case. Nor is the latter itself of so little importance as to be cast aside lightly, since it enabled me to challenge the generally accepted (localise) pathology of diphtheritic paralysis of the time, and to propose another theory of the cause of this disease, which, in the main, I think, still holds its ground. The weakest point of the case, according to the present-day critic, it would seem, is the possibility of sore throat having been overlooked, and the cutaneous sore mistaken for diphtheria. I dare pledge my word, however, that there are absolutely no grounds for any such suspicion save—*humanum est errare*—the possibility of the thing. That there was no throat affection either before or accompanying the disease the late Professor Pirrie, the patient, and myself were as certain as we could be. Therefore, the theory of Gull that the cause of the nervous sequelæ of diphtheria lay in the transmission of the disease by continuity of nerve-tissue from its seat in the throat to the upper part of the spinal cord in my opinion became untenable, and, forming a different view from the foundation of fact which my case had established, I venture to put forward another which I believed to be more in accordance with truth, and of which it was said at the time that it had "caused the pathology of diphtheritic paralysis to be remodeled." Six-and-twenty years have passed since then; yet I think if anyone should deem it worth while to resurrect this particular copy of the *Medical Times*, and read the case as described on its original pages, he will be surprised to find how little, notwithstanding the exertions of celebrated investigators and full-blown laboratories, of practical knowledge has been added to the pathological hypothesis formulated by a humble worker in the field of medicine more than a quarter of a century ago. In those days diphtheritic paralysis was of common occurrence. How is it that it is met with so seldom now? I would like to know if this is an exceptional experience.—I am, Sirs, yours faithfully,

A. ROSS PATERSON, M.D. Aberd., M.R.C.P. Edin.

Stockton-on-Tees, Jan. 22nd, 1895.

* * We insert this letter from Dr. Paterson that the inaccuracies to which he alludes may be, as they should be, duly corrected; but we see nothing in Dr. Guthrie's paper that appears to minimise the value of Dr. Paterson's case. On the contrary, the case is twice quoted as being very important.—ED. L.

During the week marked copies of the following newspapers have been received:—*Bath Journal, Carlisle Patriot, Gloucester Journal, Wolverhampton Chronicle, Swansea Journal, Llandudno Directory, Nottingham Guardian, Glasgow Evening News, Ayrshire Post, Dundee Advertiser, Times of India, Sussex Daily News, Croydon Guardian, Birmingham Gazette, South Wales Daily Star, Andover Advertiser, Leek Times, Falkirk Herald, Blackpool Times, Hereford Times, Admiralty and Horse Guards Gazette, Wigan Observer, Northern Guardian, Buxton Herald, Scottish Highlander, Woodbridge Reporter, Leighton Buzzard Observer, Bury and West Suffolk Advertiser, Cork Constitution, Cork Daily Herald, Matlock Visitors' List, Westminster Times, Warwick Times, Berwick County Gazette, Staffordshire Post, Reynolds's Newspaper, &c., &c.*

Communications, Letters &c. have been received from—

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to fictitious names or initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials &c. sent to the Office in reply to advertisements; copies only should be forwarded.

Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed. THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Annecy, France.

ON

EXPERIMENTAL CRANIOTOMY AND
DIAGNOSIS OF CEREBRAL ABSCESS.By PROFESSOR AUGUSTO MURRI, M.D.,
PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF BOLOGNA.*Delivered on Nov. 30th, 1894, before the Lombard Medical
Association, and specially reported and translated
for THE LANCET.**(Concluded from page 211.)*

PERHAPS it will seem to some that I have brought forward examples too remote to sustain my theory. And, in fact, when one cares to turn over the chronicles of medicine one can always manage to put together half-a-dozen cases which seem made on purpose for one's own theories. But I have taken my observations only from my own unfortunately narrow experience; I have not chosen them from among hundreds. Nor can I deny that cases less obscure than these often occur. The diagnoses which ordinarily answer best are those which rest on suppurative otitis. Yet, nevertheless, even in these cases, which are the most favourable, judgment is difficult. Gowers,¹ a man of wide clinical experience, writes: "The difficulty of distinguishing the existence of a cerebral abscess in a case of chronic disease of the ear is often very great, since certain general cerebral symptoms, amongst which is optic neuritis, may sometimes be produced by disease of the ear. Indeed, it is impossible to give any certain diagnostic rule in these cases. An important fact is that such cerebral symptoms, especially in severe cases of optic neuritis, are very rarely the result of disease of the ear, and in the great majority of cases in which they are found there exists an abscess." As a point of fact, there is a rule—i.e., to eliminate (treating and healing) the disease of the ear, and then to watch whether with it the cerebral symptoms also disappear. But until this elimination is affected (and the process is not easy) a rational distinction between a simple disease of the ear and otitis with consecutive abscess of the brain is often most difficult. Jansen, in giving an account of six assured cases of chronic cerebral abscess out of 13,000 patients studied in the clinic for diseases of the ear at Berlin, frankly confesses that only one of these abscesses was accurately diagnosed, and in that one the position was not determined; two other cases were decided to have intracranial complications without further diagnosis, "and in the rest of the cases" (I use his own words) "the post-mortem was a surprise to them."² Scheier, too, relates the history of a patient operated upon for suppurative otitis media, in whom the total disappearance of the symptoms had led to the belief that nothing existed within the brain, in which case nevertheless an abscess was found,³ a fact which proves that even after the elimination of the disease of the ear the doubt may still remain. Yet decidedly one cannot believe that surgeons so experienced in diseases of the ear could have lacked the knowledge or attention needed to mark the dreaded symptoms of the complications of suppurative otitis. Those ignorant of the difficulties of such criteria, as a rule, speak more certainly, and sometimes even hit the mark; but this is a proceeding utterly incompatible with science and good work. Diagnoses are made and admired as brilliant which show nothing but arbitrary assertions doomed to be disproved; sometimes there may be a fortunate one. What wonder that it should be so? But that which Bacelli has so well defined as the supreme power of experience is not a blind event, not a kind of game in the dark; it is instead the rare faculty of seeing rapidly and accurately the relations of clinical facts, and by logical analysis unravelling their remote origins. The description commonly given of cerebral abscess agrees with the acute or subacute cases met with by the surgeon.

Our learned D'Antona⁴ not long ago wrote that "a group of infective general disturbances belonging only to the abscess

help us to distinguish its course from that of a tumour, when the two processes in other ways are similar or confused. While the course of a tumour is essentially chronic and limited to local action, that of the abscess is never unaccompanied by subacute action." Yet more decidedly Dieulafoy teaches that "fever is constant in encephalitis."⁵ Many others affirm the same thing. If the clinic could sanction such sentences, differential diagnosis between tumour and abscess would not be difficult; but instead experience teaches that there are sudden deaths caused by abscesses as well as by tumour. Martius narrates the case of a nun who suddenly fell into a stupor with a slow pulse and difference of pupils, and who died the same evening as they were putting her to bed. A huge old abscess was found in the brain. The truth, therefore, is that from an acute and sudden course to a very chronic one nothing is impossible in the case of abscess, and the physician who really desires to be practical must keep account of these frequent occurrences and not diagnose tumour, hæmorrhage, tuberculosis, or cerebral inflammation without asking himself if possibly beneath the special manifestations of the case under treatment there may not lie hidden one of those less frequent and chronic abscesses of the brain. He will take note of the height of temperature not only as possible in the chronic abscess, but as favouring this judgment rather than that of any of those other diseases which are apyretic; but he must also remember that prolonged or high fever is very rare in cases of abscess; that, indeed, if there be a high temperature and the diagnosis of chronic abscess is possible, he will be led to suspect one of those complications which belong to it, for of itself the chronic abscess tends rather to produce a temperature below normal; and I here present to you, to prove this, the temperature charts belonging to two of the patients. That of one shows some periods of almost normal temperature, alternating with others of subnormal temperature, showing the successive increase of the inflammation, quickly followed by the lowering of the temperature. That of the other shows little but temperature below normal, and it refers to a case of a purely chronic abscess. Certainly such a phenomenon could not be foreseen, and it is exactly for this reason that the precept is so rooted in the minds of physicians that the temperature must rise with an abscess. To discuss the origin of this tendency of chronic abscess to lower the heat of the body would be difficult and would lead to very little conclusion. We know now that our organism can produce not only phenomena which increase heat, but also others which diminish it; perhaps it is from the nature of the chemical compounds of the brain that inflammation more often produces a diminution of heat rather than an increase. Inflammation undoubtedly gives rise to pyrogenous matters, but the organ upon which they exert their action also decidedly coöperates in the formation of their products, and these differ according to the materials which it supplies to them. It is a fact that the general effect of the action of inflammation is pyrexia; but, on the other hand, do the liver, the lungs, and the peritoneum when invaded by them give rise to a similar pyrexia? Nor must it be fancied that my thermographic charts display any singular features, since the same experience has happened to others, amongst whom it is enough to cite Hulke and Macewen. Consequently, without exaggerating the importance of the fact, it seems to me that we might rather say that a subnormal temperature of long duration, and not pyrexia, is an accurate sign of the chronic abscess of the brain.

Another feature which appears to be a part of this process consists in the apparent recovery of which the disease is capable. A neoplasm, a parasite, or an aneurysm of the brain can also have periods of inactivity, but the disorders caused by them in the functions of the brain, being for the most part mechanical, are more apt to increase than to diminish. Incipient encephalitis instead has a tendency to cause irritation around it, but once the pseudo-membrane is formed the irritation of the surrounding tissues grows less, the contents of the sac are partly absorbed, and thus the compression which it had exerted diminishes. It is no wonder, therefore, that the physiological effects of the compression should be allayed or even disappear. Naturally this period of rest or absolute silence can give no occasion for diagnosis; but when the functional disorders grow active again, which may not be for months or years, then the record of the cerebral disturbances which had first

¹ A Manual of Diseases of the Nervous System. London, 1893, p. 485.² Berliner Klinische Wochenschrift, 1891, p. 1164.³ Ibid., 1893, p. 887.⁴ La Nuova Chirurgia sul Sistema Nervoso. Napoli, 1894, vol. II, p. 232-233.

No. 3787.

⁵ Traité de Pathologie. Paris, 1894, 7ème édition.

arisen, and then disappeared or considerably lessened, might have great importance in the forming of a judgment. No less valuable would be the statement that some of the most important etiological influences had acted upon the organism of the patient. But in laying stress upon the past history we must not forget that these facts may be lacking even in cases where the action of the common causes of the abscess had not been wanting; sometimes the memory of the patient, sometimes the little importance one attributes to certain facts, is the cause of the deficiency of bygone data; but, above all, it must be borne in mind that the most insignificant occurrences, such as rhinitis or one of the commonest and slightest infective diseases, are enough to furnish the stimulus required to bring on a cerebral abscess. Another important consideration is the character of the cerebral disorders manifested at the "recurrence," as I may call it. The latent chronic abscess can increase rapidly and give rise to functional disorders; but these, being produced by the acute increase of intracranial pressure, have no special feature in the case of an abscess. At other times, however, the pus succeeds in escaping from the capsule which for a long time has retained it, insinuates itself into the healthy brain and inflames it, indeed, sometimes reaches the meninges or the ventricles, in which case symptoms occur which arise not from the abscess, but from acute encephalitis, severe meningitis, or from the breaking of the pus into a ventricle. In all these cases there is, nevertheless, the simultaneous action of a rapid increase of cerebral tension, but the preceding processes have some distinctive traits. The danger of confusing such effects of chronic abscess lies entirely in the possibility of being ignorant of the pre-existence of a cerebral lesion, for it is easy to mistake encephalitis or meningitis as being the first symptoms. If, on the other hand, the pre-existent lesion is known, the predicted succession of events increases in value, for neither a neoplasm, a parasite, softening, nor hæmorrhage is enough to give rise to acute inflammation of the brain and meninges.

A fortunate conjunction of symptoms for diagnosis of chronic abscess would be the following. A patient who, some time before, has been exposed to some condition which would cause an intracranial abscess, relates that he has suffered from headaches, fever, vomiting, slight delirium and stupor, or even simply tells us that he had had an illness which had been known as influenza or typhoid fever or rheumatic fever; that he recovered, but had remained slightly anæmic, with headaches now and again; that his mental activity seemed less, his memory less good, and his strength not so great; that, nevertheless, these facts had not been considered otherwise than as attributes of a state of health only relatively good. But suddenly phenomena arose which bespoke acute cerebral lesion, with a normal or, better still, sub-normal temperature, regularly interrupted by slight elevations of temperature. The suspicion of an abscess which had arisen in the brain would then be absolutely rational. Or that a moderate and continuous fever sets in; the functions of certain cranial nerves suffer in a serious way, and through a peripheral lesion; and epileptiform fits occur,—then the diagnosis of chronic cerebral abscess which has reached the meninges becomes quite probable. The value of such a past history would, without doubt, be great; it would almost give us the clue to the source and ulterior changes of the abscess. Unfortunately, in real cases either this history is wanting altogether or exists only in fragments of which the wisdom and caution of the medical practitioner will not permit him to avail himself. But if the history is altogether devoid of suggestion, little can be got from the facts which are offered by the present state. I think that the first cause of the symptoms, even in the abscess, is the mechanical action exerted upon the healthy brain; but this action is common to many other morbid states. Some affirm that the abscess does not exercise so strong a compression as the tumour, but that answers only for small abscesses; it is enough to have seen the brain of one who has died of suppurative encephalitis to be persuaded that the compression may be extremely great. There are others who maintain that the elements of the brain are destroyed by the abscess, and that this is not so much the case with the neoplasm; therefore, the abscess would offer more symptoms of failing function (Anfallsymptome) than does the tumour. The latter would seem to compress and irritate, not destroy. But even such an affirmation as this is not always true, for the tumour can also destroy. The not infrequent latency or semi-latency of the abscess proves that symptoms of imperfect function do not prevail in it. Symptomatic differences are more to be

expected from the diversity of action which morbid processes, essentially different in themselves, must exercise on the surrounding nervous elements. But this scientific presumption is by no means sanctioned by clinical experience. It has been said that the headache belonging to abscess is circumscribed; but the fact is rare, and when it does so happen the headache depends more upon the local pachymeningitis than on the abscess; and since local pachymeningitis may often have other causes, the headache caused by it is not altogether to be attributed to an abscess. Others would wish to give greater importance to pain on percussion of the head, but even this fact rather reveals the participation of the dura mater and the bone—a participation which can also occur in neoplasms and produce the same effects. A slow pulse and Cheyne-Stokes' respiration have often been noticed, but these symptoms seem to depend solely on the increased pressure on the bulb. The power which abscesses possess of increasing intracranial pressure, as I have repeated several times, is the attribute of many other morbid processes of the brain. Perhaps the prevalence of abscesses in the cerebellum, and perhaps, too, large abscesses in the temporal lobe, might more easily account for a more direct pressure of the purulent collection upon the centres of the heart and respiration, but in any case it is certain that this phenomenon may equally belong to all other processes which increase intracranial tension.

The pretence of bringing forward symptoms of interference with function to strengthen a diagnosis of abscess would scarcely warrant mention were it not for the fact that we meet every day with some writer who relates that, guided by these phenomena, he was able to discover the presence of an abscess in the brain. It is evident that we are treating of happy coincidences, not of rational judgments. What is a symptom of interference with function if not an impaired function of some part of the brain? And why would this loss of function be the effect of an abscess and not of the other morbid states, which, like the abscess, can alter the physiological conditions of that area of the organ which governs it? At the best, one can but say, on behalf of this distinction, that if the symptoms of interference pointed to the cerebellum or the temporal lobe, such a fact would favour the diagnosis of abscess, because this latter has a great tendency to develop in the two aforesaid situations; but everyone must see the fallacy of such an argument. The opinion which can be formed on the degree of lesion of the optic nerves is, perhaps, more accurate. I never remember to have seen an absolute amaurosis caused by abscess, except in the last stages, yet it is not infrequent in cases of tumour. Many also affirm that the optic nerves are more often injured by the presence of a neoplasm than by an abscess; but I know nothing of the proofs of this. On the other hand, it seems true that the changes in the ocular fundus are less pronounced in abscess (Gowers). B. von Beck attributes this difference to the different duration and intensity of the compression and of the venous stasis, but even here I must note that an abscess may last as long and compress as much as a tumour, if it is chronic and large. It has already been said that abscess more often than tumour causes unilateral lesion of the optic nerves corresponding to the affected half of the brain; but among the few cases narrated by me there is an example which precisely indicates not only the absence of this tendency on the injured side, but exactly the contrary. Besides this, I have had occasion to see a case of real Leber's "papillitis," so that, considering how in a cerebral tumour the lesion of the optic nerves varies from the greatest papillitis down to the slightest papillo-retinitis and to normal conditions, it is necessary to note that the different degrees of alteration in the optic nerves happen also in many cases of abscess. It is remarkable that Korner,⁶ although he writes of the most favourable cases being preceded by otitis, also affirms and demonstrates the "diagnosis of cerebral abscesses preceded by otitis is, as a rule, often impossible." To demand, therefore, a sure diagnosis, or even a very probable one, of chronic abscess of the brain shows an imperfect knowledge of the clinical facts which concern it, and means that either we must deliberately renounce the cure of even one of these patients, or that we must resign ourselves to explorative craniotomy. The merit of having dared most belongs to Horsley, Macswen, and the English surgeons in general, but their example has not yet been imitated by many physicians or many surgeons. Even

⁶ Die Otitischen Erkrankungen des Hirns. Frankfurt-am-Main, 1894, p. 111.

an illustrious surgeon like Bardeleben leaves a young man of twenty-six, for whom a diagnosis of abscess was made, to die, because the abscess was probably multiform and seemed extensive;⁷ and a clever physician, Baginsky, referring to the treatment of cerebral abscess by means of trephining, says frankly that "he did not wish to submit the patient to operation until the phenomena were absolutely imperative (*absolut dringend*)."⁸

Why refuse the operation? Why delay it even when diagnosis advises it? The excellent results obtained by Macewen are probably owing to speedy and frequent operation. Comparing the results of the treatment used in one of the most renowned surgical clinics, that of Heidelberg, one finds a marked difference between them and the most fortunate "experiments" of the Glasgow surgeon. From among eleven patients for encephalitis who entered Czerny's clinic during the last four years, one only was speedily operated upon, and was the only one to recover. The other ten all died, notwithstanding the fact that five of them had been operated upon by skilful hands. It is certain that if the pus is not removed till it has already devastated the brain, these devastations alone are enough to kill the patient. A probably perfect diagnosis is the guide for operation, the surgeon may perform it in a masterly fashion, but for the patient the operation will have become useless. Scientific exactness must then give place to practical utility. If there are surgeons who withhold their help to patients whose last chance it is, we must believe that they do so through fear of doing more harm than good. Is this fear justified? Bergmann has admirably demonstrated the perils of craniotomy, but successive experience has lessened the degree of danger. Even in the extraction of large tumours Brahman and Czerny have proved that the operation can be successfully performed. But cerebral abscess presents even fewer dangers than a tumour. I know that even to surgeons sincerely devoted to antiseptis it is not always given to avoid purulent meningitis. These cases are few, however, and will certainly diminish as precaution is greater; they may even entirely disappear. When we think of the wretched state of one who carries a mass of decomposition in his brain we can scarcely imagine anything worse for him. Incision of the brain, when performed with all the precautions which have rendered modern surgery so efficacious, is not succeeded by ill effects, even if the abscess be not evacuated—indeed, even in these less fortunate cases it may diminish suffering—nor can we always ascribe the benefit that ensues to the process for which, as a palliative, Horsley recommended puncture of the brain.

Professor Bergmann refers to Drummond's attempt to find an abscess which really existed. Well, he narrates that "trotz mehrfacher Punctionen" on the day after the operation the patient was conscious, his speech had returned, convulsions ceased, paralysis was gone, and yet the abscess had not been reached by either of the punctures.⁹ The eminent clinician also mentions one of his own patients in whom several punctures made to a considerable depth did not succeed in reaching the abscess. Nevertheless, the condition of the patient remained unchanged for three days, after which pus began to issue from one of the channels opened by the cannula.¹⁰ Czerny operated on a young man in whom he had made the diagnosis of abscess in the cerebellum, but found in the cranium neither pus nor anything else abnormal. After two months, whether in consequence of this operation or in spite of it, the young man was quite cured of the disturbances which had made them suppose an abscess existed, and which they afterwards interpreted as dependent on Menière's disease.¹¹ We could easily multiply facts by similar cases, but it is only needful to refer to one more. It belongs to Barker, and is also quoted by Bergmann.¹² Barker, believing an abscess to exist in the cortical centre of the facial nerve, applied the crown of the trephine not only once, but twice, to the motor region, but found no pus. Firm in his convictions, he tried it a third time further back, and found the abscess in the temporal lobe, and cured his patient. Facts like these show that even where the diagnosis of situation is mistaken the intention of the treatment might follow. The condition of the abscess in regard to explorative craniotomy is more favourable than that of the tumour, not only because its situation in the deeper parts is no obstacle to its treatment, but also because puncturing offers us a valid means of

correcting an erring diagnosis of its site. In the very first words of his treatise, Starr asserts that if the diagnosis of the nature of a cerebral process and of its seat cannot be certified, the surgeon must not be asked to operate; but when he comes to speak of abscess, he repents, and says that "even if the seat is uncertain it is the duty of the surgeon to explore."¹³

Truly admirable was the work of a bold and clever modern surgeon. Here is an example: On Sept. 15th, 1891, Macewen operated on a lad of sixteen years in whom cerebro-spinal meningitis had been diagnosed. He opened the mastoid and the base of the cranium to discover the dura mater corresponding to the under part of the temporal lobe. The dura mater and pia mater were incised and the exudation evacuated. The second operation was on Oct. 3rd. The dura mater was laid bare over the lateral sinus and the cerebellar fossa, a cannula was inserted in the temporal lobe, but no pus was found. Four days later a third operation was performed. The dura mater was again opened and the cerebral tissue once more perforated; the abscess was found and its cavity cleansed. But on Nov. 19th it was necessary to operate for the fourth time. A bony disc was removed from the squamous portion of the temporal bone, the dura mater again opened, the superficial cerebral tissue again incised, and another abscess emptied and its cavity washed. Notwithstanding a chronic pachymeningitis, an acute leptomeningitis, encephalitis, and two consecutive abscesses, the patient recovered.¹⁴ I shall never tire of searching. Where this is possible, what excuse can be made for the physician who resigns himself to the disease or death of curable patients? I seek in vain for any reason, practical, moral, or scientific, which can absolve one who renounces the privilege of saving another's life.

My worthy colleagues, I, too, have opened the skulls of patients in whom I had correctly diagnosed tumours or abscesses, but have refrained from giving you their history. It would have been certainly less humiliating to me and perhaps less tiresome to you. Secure in your indulgence, I have preferred this more tedious way to reach a conclusion which may be of practical use. It is this. Physicians and surgeons, we must apply our skill more largely to the benefit of the patient; those who suffer from brain diseases have not yet learned to consult the surgeon rather than the physician. It therefore rests with the practitioner to hold his mind always open to the suspicion of chronic cerebral abscess and to invoke the brotherly aid of the surgeon; but it is as yet irrational to ask that he shall be all-knowing of the real state of things, and pretend to perfect precision; the surgeon must accept the arduous honour of completing both diagnosis and cure. In this way hundreds of sufferers who now die will be restored to life. In times when we so often see the harm produced by irrational hysterectomy and ovariectomy, need we still so much dread exploratory craniotomy, which promises such great results? No one can so well respond to this as yourselves, an assembly of men who live to think and to act. I invoke your instruction. Individually, the field of experience is too restricted to carry out this beneficial reform in practice; collective work is necessary; and if my words have had power to convince you I can hope for no wiser and more cordial coöperation than that which you have it in your power to give.

ON SUPPRESSION OF URINE IN DIPHTHERIA.

By E. W. GOODALL, M.D. LOND.,

MEDICAL SUPERINTENDENT OF THE EASTERN FEVER HOSPITAL, HOMERTON.

THE discovery and the recent extensive adoption of the antitoxin treatment have stimulated the study of diphtheria from all points of view. This paper, commenced upwards of a year ago, deals with certain of the symptoms of that disease, and its publication is prompted, not by the rarity of the cases recorded in it (for, in truth, such cases are common enough), but by the facts, firstly, that little attention has hitherto been paid to them, and, secondly, that of late the suggestion, if not actual assertion, has been made

both in this country and in Germany that these very symptoms—amongst which anuria is prominent—are due to antitoxin.

CASE 1. *Diphtheria, faucial and nasal; total suppression of urine for nearly seventy hours before death.*—The patient was aged nine years. She was first taken ill on Oct. 22nd, 1893, and was admitted into the Eastern Fever Hospital, Homerton, on Oct. 25th. She was suffering from a malignant type of diphtheria; there were intense injection and oedema of the fauces, on which there was a thick sheet of membrane. There was a discharge from the nose, and the breath was fetid. The cervical lymphatic glands and cellular tissue were much swollen. The temperature on admission was 101° F.—Oct. 26th: She is in the same condition. The urine contains a good deal of albumen. The morning temperature was 99.4° and the evening temperature 100.4°.—27th: She has been sick four times during the night, the vomiting bearing no relation to the taking of nourishment. The pulse is 102. The patient states that she feels better, but she is actually in a critical condition. The morning temperature was 99.4° and the evening temperature 100.2°.—28th: The patient has passed no urine since 8 P.M. on Oct. 27th; before that she passed plenty of urine. The pulse is 108. 3.30 P.M.: The pulse is 72, irregular. The urine contains a good deal of albumen. 11 P.M.: The pulse is 94, a trifle irregular. The patient has only passed four ounces of urine during the day. The morning temperature is 98.6°, and the evening temperature 99.6°.—29th: No more urine has been passed; the pulse is 100 and the respiration 16. Since 7 A.M. a few red pimple-like spots have appeared on the legs. The morning temperature was 97.4° and the evening temperature 98.4°.—30th: This morning the patient is sitting up in bed knitting; she looks much better, but she is reported by the nurse to have had a very bad night, having been constantly trying to get out of bed. No more urine has been passed, even when the bowels have been moved. 12.45 P.M.: The pulse is regular and 64. The nose is blocked with thick mucus. There are patches of membranous material about the palate, uvula, and neighbouring parts, mixed with blood; these parts are in a very dirty and sloughy-looking condition. The patient is stated to have been sick thirteen or fourteen times during the night. The swelling of the cellular tissue of the neck is, if anything, less. 10.15 P.M.: She has passed no more urine. The patient sleeps much and is not so restless as she has been. The pulse is 60, irregular. The patient has been sick once during the day and once this evening. On the last occasion she brought up altered blood. 11.45 P.M.: The pulse is 66. The morning temperature was 97° and the evening temperature 98.4°.—31st: To-day there is hæmorrhage from the vagina and rectum; there is some bleeding from the gums, and a foul sanguineous discharge runs from the nose. The child is very drowsy, but wakes up and talks occasionally. The pulse at the wrist cannot be felt. She has passed no more urine. The bowels acted five times during the night. The heart sounds are faint but normal; action irregular, 72 per minute. Last night there was twitching of the left arm; this has not occurred again. The patient vomited nine times during the night; the vomited matter was like coffee grounds. At midday the child was sitting up in bed; she was quite conscious and stated she felt better. 5.15 P.M.: Drinks all return freely through the nose. The bowels have been opened seven times to-day. There is on the inner side of the right eye a small subconjunctival hæmorrhage. The pimple-like spots on the legs have become larger, and some have given rise to small pustules. A few similar papules and pustules have come out on the trunk and upper extremities. Small petechial hæmorrhages can be seen in the skin of the neck. At 7.50 P.M. the child became convulsed. There were twitchings of the muscles of the face and upper limbs, but not of the lower. These twitchings continued till death, which took place at 8 P.M. The morning temperature was 97° and the evening temperature 97.6°.—The bowels acted seven times during the last twelve hours of life; there was no urine passed on these occasions—in fact, no urine was passed for the last sixty-nine hours of life.

Necropsy, twenty hours after death.—The skin was very anæmic and waxy-looking; rigor mortis was well marked in the lower and less so in the upper limbs. The fauces were in a sloughy, blood-infiltrated condition, and it was difficult to see where membrane was attached, as it much resembled the tissues around. There was no membrane in the larynx or

lungs; the latter were normal. The heart and vessels were normal; there were no petechiæ on the pericardium. The cervical glands were swollen. In the tissue of the neck, chiefly about the sterno-mastoid muscles, there were patches of blood extravasation. There was also extravasation of blood into the tonsils and surrounding tissues. The œsophagus was healthy. The stomach contained eight ounces of partially digested blood; its mucous membrane was much congested, and beneath it there was general extravasation of blood; there were no ulcers. The intestines were normal; there was nothing in the rectum to account for the hæmorrhage during life. Here and there in the small intestines was a little tarry-looking material. The spleen was normal and not at all enlarged; the liver, pancreas, and adrenal bodies were normal. Numerous petechiæ and several extravasations of blood were scattered about between the layers of the peritoneum; there were also extravasations in the retro-peritoneal cellular tissue. The kidneys weighed five ounces and three-quarters. The capsules stripped easily; to the naked eye the only change was in the cortex, which appeared to be slightly thicker than normal. One small extravasation of blood was found on the surface of one of the kidneys; the pelvis and ureters were normal. The bladder was quite empty of urine, and contracted; in its lower and front part there was a dark submucous blood extravasation. The uterus was normal.

CASE 2. *Diphtheria, faucial and nasal; total suppression of urine for fifty-seven hours before death.*—The patient was aged four years. She was first taken ill on July 24th, 1893, and was admitted to hospital on July 28th with exudation on both tonsils and uvula. July 29th: The patient is seriously ill. There is a free, thin, slightly offensive discharge from the nose. The cervical glands on both sides are enlarged. 11.45 P.M.: She has spat out some large pieces of membrane. There is no albumen in the urine.—July 30th: There is a fairly thick sheet of membrane on the left side of the palate.—31st: The fauces are covered with membrane; the cervical glands are still enlarged.—Aug. 1st: The patient has been vomiting to-day. There is a thick precipitate of albumen in the urine.—2nd: The fauces are much swollen and injected, and upon them are small patches of membrane. There is a blood-stained discharge from the nose and mouth. The patient has passed no urine since 4 P.M. yesterday. As far as can be made out the bladder is empty. She has been vomiting frequently. The pulse is 96, regular.—3rd: She has passed no urine since the last note. She is very restless and is constantly vomiting. The pulse is 66, regular. There is no oedema anywhere. The patient is quite rational.—The child died at 1.10 A.M. on Aug. 4th. No more urine was passed. There was nothing particular to note concerning the temperature in this case.

Necropsy.—The kidneys were described as being "slightly swollen and a little congested."

CASE 3. *Diphtheria, faucial and nasal; almost total suppression of urine for nearly forty-two hours before death.*—The patient was a boy aged four years and a half. He was admitted on the evening of Dec. 15th, 1893. He had sore-throat on Dec. 13th. On his admission the fauces were found to be a little red; no membrane was to be seen; there was a nasal discharge and the breath was foul. The glands on both sides of the neck were enlarged. The patient did not seem to be seriously ill.—Dec. 16th: The urine is free from albumen.—17th: The patient has become much worse. There is now a large patch of membrane on the left anterior pillar of the fauces, left tonsil, and left side of the soft palate. The glands are larger.—18th: The condition is as yesterday; but the urine contains albumen.—19th: The patient passed about six ounces of urine at about 6 P.M. yesterday; none has been passed this morning. He vomited once yesterday, and twice in the night. There is a large patch of membrane on the left side of the palate, extending to the left tonsil. This patch is very thick and looks like wash-leather. There is a quantity of nasal discharge, which is offensive. The urine is loaded with albumen. Midnight: He has vomited twice this evening; he is pale; the extremities are cold; no more urine has been passed since last night. The nose is blocked. The pulse is about 90, regular, and very small at the wrist. The patient is now very drowsy, but has been wide awake all day. There is slight oozing of blood from the nose. The patient remained in a drowsy condition after the last note was made until the time of his death, just before noon the next day, Dec. 20th. The bowels acted three times, and he passed about half an ounce of urine with the stools, which was all he passed

¹ From Guy's Hospital Reports, vol. I.

within the last forty-two hours of his life. There was also vomiting on three or four occasions during the last twelve hours, independently of food. The temperature was 102° F. on the evening of Dec. 16th, 100° next day, and afterwards normal. A post-mortem examination was refused.

CASE 4. Diphtheria, faucial and nasal; total suppression of urine for twenty-two hours, partial for some days before death.—The patient was aged three and a half years. She was first taken ill on July 21st, 1893, and was admitted on July 22nd. She did not appear to be seriously ill. There was a casing of membrane round the uvula; the edge of the right side of the soft palate was irregular in appearance and was bleeding slightly. There was a thick nasal discharge. The urine was loaded with albumen.—July 23rd: There is less membrane. The amount of urine is diminished.—24th: The fauces are as yesterday. The urine contains much albumen. Eleven ounces were passed to-day.—25th: The patient has been vomiting. Pulse 102. There is no membrane now. Ten ounces of urine were passed to-day.—28th: The patient is constantly sick. There is no membrane, but there is an appearance as of ulceration along the edge of the palate and uvula. 9.30 P.M.: The patient has been sick several times during the day and has passed no urine since the early morning, when six ounces were passed. Pulse 104, regular. The child is much worse.—27th: Pulse 92. The patient is still vomiting. Six ounces and a half of urine were passed at 5 A.M.—28th, mid-day: There has been less vomiting during the last twenty-four hours. Pulse 92. The patient has only passed seven ounces of urine since the last note. The urine contains much albumen. Fluids return through the nose when the patient drinks.—29th: The pulse is irregular. The patient is very drowsy. She vomits at times. Drinks return by the nose. 11.45 P.M.: Pulse 108, very small; heart quite regular. There is a systolic apical bruit, and the pulmonary second sound is accentuated. Seven ounces and a half of urine have been passed to-day.—30th: The patient was sick last night after taking some jalap powder. She has been vomiting again this morning. Pulse 112, quite regular. There is a systolic apical bruit, but I cannot make out any cardiac dilatation. The urine is of a natural colour, but contains a considerable amount of albumen. Eight ounces were passed to-day.—31st: The patient seems worse to-day; her extremities are very cold. Pulse 120, regular. She has been frequently sick this morning. Ten ounces and a half of urine were passed during the day. The urine contained a thick precipitate of albumen.—Aug. 2nd: Vomiting is almost constant now. The child is extremely restless. She died at 3.40 A.M. in convulsions.—Four ounces of urine were passed at 5.30 A.M. on Aug. 1st; from that time till death no more. The patient's temperature varied from 97° to 99° 8' F.

Neurology.—Permission was granted only to remove the kidneys. To the naked eye these organs were quite normal.

CASE 5. Diphtheria, faucial and nasal; partial suppression of urine for four days before death.—The patient, a boy aged six years, was admitted into the Eastern Hospital on Jan. 3rd, 1894, in the afternoon. His illness began with vomiting on Dec. 29th, 1893, and there was sore-throat on the 30th. On admission there was membrane on both tonsils, which were swollen; the patient's breath smelt very offensively, and there was a copious thin discharge from the nose. The cervical glands on both sides of the neck were enlarged. The evening temperature was 100 4° F.—Jan. 4th: The pillars of the fauces and tonsils are swollen and injected, and their surfaces are marked by several superficial ulcers. Nothing was seen this morning that could be positively called false membrane. The tongue is thickly furred. The urine contains a heavy precipitate of albumen. Morning temperature, 100 8°; evening temperature, 99°.—5th: The urine is loaded with albumen; urates are present. At 1.30 P.M. the pulse was 124. Morning temperature, 99 8°; evening temperature, 100 2°.—6th: The urine is loaded with albumen. The patient vomited four times in the night. There is membrane to day on both anterior pillars of the fauces. Morning temperature, 99 6°; evening temperature, 99°.—7th: Morning temperature, 98 6°; evening temperature, 98 4°.—8th: There is still a heavy precipitate of albumen in the urine. There is membrane on the uvula and lining the pharynx and tonsils. At 2 P.M. the pulse was 102. Morning temperature, 98 6°; evening temperature, 98 8°.—9th: Morning temperature, 98 2°; evening temperature, 97 8°.—10th: The patient is slightly drowsy. Pulse 66, weak, regular. He vomited twice in the night; he has become very pallid. The urine is pale and clear, and contains a flocculent precipitate

of albumen. Midnight: Pulse 66, regular, soft. Morning temperature, 97 4°; evening temperature, 96 6°.—11th: The patient has vomited once during the night (after taking milk) and once this morning. He is not drowsy to-day, but is amusing himself with looking at pictures. There is still some nasal discharge. The pulse is very intermittent and soft; the heart intermits at every third beat. The rate is about the same as yesterday. There is only an opalescence of albumen in the urine. 5 P.M.: Pulse 62. The patient has vomited again once. Morning temperature, 97°; evening temperature, 96 8°. Midnight: Pulse, 58 to 60; respiration, 16.—12th: The pulse as counted by auscultation, 64. The heart is very irregular; there are occasionally no beats for a period of four or five seconds. The patient takes very little nourishment. He has vomited twice during the night and once this morning. There is some emaciation. The pulse cannot be felt at the wrist. There is a considerable amount of albumen in the urine, which is pale and clear. Some of the urine from the bottom of the vessel was microscopically examined, though there was no definite deposit. Nothing abnormal could be detected. Morning temperature, 97 4°. At 4 P.M. the heart-beats as counted by auscultation were 46 per minute, and regular in rhythm. The first sound of the heart was faint. The patient died at 4.35 P.M. He retched several times, and vomited a little brown fluid during the last half-hour of his life. He was rational, though perhaps a little dazed, up to the end. Some difficulty in keeping him warm existed for the last two days, though he was wrapped up in blankets and had hot water bottles in his bed. During the last twelve hours he resisted all attempts to feed him. He had lost flesh rapidly, and the progressively increasing pallor was very noticeable. Towards the end the respirations were "sighing" in character. At different hours on Jan. 11th and 12th the pulse-rate was as follows:—Jan. 11th: 9.30 P.M., 58; midnight, 60. Jan. 12th: 3 A.M., 58; 6 A.M., 56; 9 A.M., 54; noon, 64; 3 P.M., 48; 4 P.M., 46. The amounts of urine passed during each day were as follows (opposite them are placed the pulse-rates):—

Jan. 5th	oz.	Pulse.	Jan. 10th	oz.	Pulse.
5th	18 1/2	124	10th	5	65
6th	13 (about)	—	11th	5	62 to 58
7th	12	—	12th	1 1/2	58 to 46
8th	13	102			(once 64)
9th	8 1/2	—			

The amounts passed between 8 P.M. on one day and 8 P.M. the next were measured, so that the above amounts commence from 8 P.M. on Jan. 4th. Only half an ounce was passed between 8 A.M. on Jan. 12th and the hour of death. The bowels were opened every day naturally, sometimes two or three times.

Neurology forty-eight hours after death, by Dr. F. G. T. Fox.—There was some emaciation of the body, and the skin was very pale. There was nothing to be seen about the fauces that was undoubted membrane; there was a large crypt-like cavity in the right tonsil, opening by a large passage on to the free surface. The epiglottis and larynx were injected and raw-looking. The lungs, bronchi, and trachea appeared to be healthy. The kidneys, which weighed five ounces and a half together, had the pyramids congested. It was questionable whether the cortex was at all increased in size. The capsule peeled readily; there was no charge visible to the naked eye in the structures. The liver was much congested and of a deep purple colour. The heart and spleen were normal. The bladder was contracted and empty.

CASE 6. Diphtheria, faucial, diminution in amount of urine.—The patient, aged six years, was admitted on Aug. 5th, 1893, having been seriously ill since the day before. There was white deposit, not definitely membranous, on the left tonsil, and much swelling of the cervical glands. On Aug. 7th both tonsils were covered with whitish deposit. The following was the amount of urine passed daily from Aug. 7th to 20th:—

Aug. 7th	oz.	Aug. 14th	oz.
7th	11	14th	14
8th	17	15th	17
9th	10	16th	12
10th	7	17th	15
11th	12	18th	14
12th	12	19th	17
13th	15	20th	20

From Aug. 10th to 21st there was albuminuria, but only once in any considerable quantity. From the 10th to the 13th the patient was croupy. On the 16th there was paralysis of the palate. Up to the 9th there was considerable pyrexia.

There was no vomiting. The patient recovered and left the hospital on Oct. 28th.

[I have not given the notes of the treatment of these cases, partly to avoid waste of space, partly because it was unavailing. But in these cases, as well as in those referred to in the following remarks, various local remedies were employed—among others, boracic acid, carbolic acid and iodine, chlorate of potash, bicarbonate of soda, and magnesium sulphite.]

REMARKS.

These six instances have been selected from the notes of many others of the same kind as examples of the class of case in which anuria occurs, and the manner in which it supervenes. The condition they illustrate is a common one, yet it is curious that the text-books say little or nothing about it. As far as I know, my former colleague, Dr. G. G. Morrice, was the first definitely to draw attention to the suppression of urine in diphtheria.² Cadet de Gassicourt does not mention it. Hænoch, who speaks of "nephritis" in diphtheria, says only that one of the symptoms is a "diminution in the quantity of urine." Oertel³ refers to fifty fatal cases of diphtheria recorded by Bartels, in most of which there were dropsy and suppression of urine. But, as is observed by Fagge,⁴ doubt must be raised as to whether some, if not all, of these cases were not scarlet fever. Dr. Morrice refers to a paper by Dr. Gee.⁵ Dr. Gee's paper was written to draw attention to the gravity of repeated vomiting in diphtheria; but in three of the cases he records it is expressly mentioned that the urine was scanty and in three others that there was evidence of renal affection. In two of Dr. Morrice's six cases no mention is made of the quantity of urine.

It will be observed that there are certain points common to the six cases detailed above. They were all severe cases, with much local affection. There was albuminuria and more or less complete anuria. In the fatal cases there was frequent vomiting, and death was due to cardiac failure. This combination of symptoms is common in diphtheria. Some time ago I analysed the notes of thirty cases coming under my notice during the years 1892 and 1893, in which anuria was present in a marked degree. All these cases save three were fatal. I shall have occasion to refer to them in the course of my remarks.

Anuria.—This may be partial or complete. In 7 of the 30 cases there was total suppression of urine for from eighteen to nearly seventy hours before death; while in 12 others suppression was nearly complete for from twenty-four to seventy-two hours. Sometimes the excretion of urine is suddenly arrested; at others the period of total or nearly total suppression is preceded by one of gradual diminution in the amount excreted. In all cases there is albumen, often in large amount. The urine is of normal appearance, and rarely is there any sediment. Blood is never present. I have known anuria to set in as early as the third, and as late as the tenth, day of the disease.

Vomiting is often present, and was observed in 23 of the 30 cases. In 15 instances the vomiting was frequent. In 7 of these 15 cases vomiting set in simultaneously with anuria, before it in 4 (one to three days before), after it in 4 (two to four days after). The vomiting is quite independent of the taking of food. Only occasionally is there diarrhoea, but constipation is common.

Symptoms of cardiac failure are nearly always present from the time when the suppression of urine commences. The radial pulse is soft and small, and the cardiac sounds are faint. These symptoms are usually of gradual onset. The pulse at the wrist becomes more and more imperceptible to the touch and may be quite indistinguishable for some hours before death. The pulse-rate may during the same time become lowered; in seven instances it fell to below normal, the lowest rate observed being 44 per minute; but absolute infrequency of pulse-rate is not a constant feature of these cases, though there is often relative infrequency compared with the rate observed earlier in the course of the disease. Irregularity of cardiac rhythm is occasionally met with.

Death occurs often by sudden cardiac failure; in seven of the thirty cases it was immediately preceded by convulsions. At other times death is by slowly progressive cardiac failure. The patient's extremities become markedly cold and his skin and lips pallid; his temperature falls below normal; he is drowsy, but can easily be roused, though he resents being

disturbed. In these cases the end comes with such quietness that it is difficult to tell the exact moment of death. The fatal termination occurs most often on the seventh, eighth, or ninth day of the disease. In the thirty cases the extremes were the sixth and seventeenth day.

There is usually *much local exudation* upon the fauces. In twenty-three of the thirty cases there was evidence also of nasal diphtheria. The local exudation may entirely disappear before suppression of urine sets in. Even in cases where the exudation persists serious constitutional symptoms may not show themselves until the onset of anuria. To the inexperienced observer the patient may, in those cases where the membrane clears off and there is little if any vomiting, seem to be improving, and I have more than once had to warn a patient's relatives of the fallaciousness of appearances.

Post-mortem appearances.—In fatal cases of diphtherial anuria there are only two constant conditions observed at the necropsy, and they seem to be of little importance. The one is marked pallor of the skin and lips, the other a contracted and empty bladder. The kidneys are usually normal in every respect to the naked eye. Now and then they are paler than usual; very occasionally the cortex is slightly increased in width. In cases where the membrane has cleared off from the fauces before death there may be absolutely no morbid condition to demonstrate post mortem the nature of the disease.

What is the cause of these symptoms? The vomiting and pallor, taken in connexion with the albuminuria and scantiness of urine, suggest uræmia. Certainly anuria is enough to account for uræmia. What, then, is the cause of the anuria? It is stated by Dr. Morrice, in the paper to which I have already referred, that in the cases I am discussing the kidneys are found to be in a state of acute nephritis, and to this condition he evidently attributes the suppression of urine. He is supported in his view of the matter by the fact that certain other writers on diphtheria also speak of nephritis—Hænoch⁶, for example. On the other hand, Cadet de Gassicourt⁷ (who twice in one short chapter talks of the *bénignité habituelle* of the albuminuria of diphtheria) declares that among upwards of a thousand cases of diphtheria observed by himself he saw only three fatal from nephritis, and Dr. Goodhart⁸ states that the kidneys do not usually show any definitely marked change. There is thus much divergence of statement even as to facts. Now, clinically, these cases of diphtherial anuria differ widely from cases of acute nephritis. In the Eastern Fever Hospital, Homerton, into which very many patients suffering from scarlet fever or from diphtheria are admitted in the course of the year, there is ample opportunity of observing this difference. In acute nephritis hæmaturia, dropsy, pyrexia, convulsions (occurring during the course of the attack, and not merely just before death), and coma are common; in the anuria of diphtheria these symptoms are never met with. In nephritis there is usually recovery at the end of several weeks, or a chronic nephritis may result, and even in fatal cases death occurs after an illness of some duration, whereas in diphtherial anuria the usual termination is in death within a few days or even hours, and, in the cases which recover, recovery is always complete. In order to emphasise the difference between acute nephritis and diphtherial anuria I may mention that I have five times seen acute nephritis complicate an attack of diphtheria, and in these five cases the symptoms of the renal lesions were precisely the same as are seen in nephritis after scarlet fever. Lastly, treatment, such as is of great value in nephritis, is of absolutely no use whatever in the suppression of diphtheria. Clinically, therefore, diphtherial anuria is very different from acute nephritis. The evidence derived from the bedside is supported by that gained in the deadhouse. As I have already stated, to the naked eye the kidneys appear to be normal. With the microscope, also, little is to be found amiss. I have examined in this way ten cases, of which three were Cases 1, 4, and 5, described above. In some the kidneys were normal; in others there was a slight infiltration of the interstitial tissue with leucocytes, either around the Malpighian bodies or between the tubes; in two cases where fresh sections had been stained with osmic acid, slight fatty degeneration of the cells of the convoluted tubes was observed; but in another case which I have quite recently examined in this manner no such change is visible. In short, what

changes are seen are variable and slight, and I would suggest that they are secondary to the greatly diminished flow of urine through the organs. The anuria is not, therefore, dependent upon nephritis. It is too marked to be due to either the vomiting (which is not always present) or the cardiac failure. I confess to being ignorant of its exact cause, and can only suggest that it may be due to the direct action of the poison (or poisons) of diphtheria upon the nervous mechanism that governs the excretion of urine.

A CASE OF TUMOUR OF THE CORPORA QUADRIGEMINA.

By L. G. GUTHRIE, M.D. OXON.,

AND

W. ALDREN TURNER, M.D. EDIN.,

PHYSICIANS TO OUT-PATIENTS, THE HOSPITAL FOR EPILEPSY AND PARALYSIS, REGENT'S PARK.

CASES of tumour of the corpora quadrigemina are sufficiently rare to warrant the publication of one, which was studied for some weeks during life, and in which a post-mortem examination was obtained. We have collected about twenty cases of this condition scattered throughout medical literature, in some of which the tumour produced only partial destruction, while in others an extension of the growth involved neighbouring structures, such as the adjoining parts of the optic thalamus and the tegmentum. The case which we here record was characterised by the completeness of the destruction of the quadrigeminal bodies, with only slight implication of one optic thalamus and none at all of the tegmentum.

A piano-maker twenty-three years of age was admitted to the Hospital for Epilepsy and Paralysis, Regent's-park, on Sept. 6th, 1893, under the care of Dr. Guthrie, in the absence of Dr. Hughes Bennett, who has kindly allowed us to publish the case. The following history was obtained from the patient's mother. He had always been well until three years previously, when he had an attack of earache, followed by slight discharge from the right ear. The discharge lasted a few days only, and he had no further trouble from that source. In the second week of June, 1893, he complained of constant frontal headache, but he was able to continue work, and left London to take a situation in Birmingham on June 17th. On June 28th, the headache still persisting, he consulted Mr. Addenbrooke of Birmingham, who kindly sent the following particulars. "He complained of frontal headache and giddiness. He had no squint at that time, but it developed in a week or two. It was very difficult to get any family history from him, but I afterwards found out from his brother that he had lived rather a wild life, and that his father was an epileptic. He had a good deal of loss of coördination of movement even then, which got worse. There was also complete absence of the knee-jerks, and the pupils responded slightly to accommodation, but not to light. He had more or less want of control over the excretions almost from the first. He had no delusions whatever whilst under my care, and gave perfectly rational answers to all questions." There was no family history of phthisis or cancer. On admission to the hospital on Sept. 6th his condition was as follows: He was much emaciated (his mother stated that the wasting dated only from the onset of the present illness). He lay on his back with the legs extended. His head was retracted and turned to the right. He resisted with a frown of pain all attempts to move it in the opposite direction. His expression was dull and listless, though not indicative of pain; but if asked whether he was in pain he always answered "Yes," or nodded assent, placing his hand on his right temple to localise the site. There appeared to be some tenderness about the right occipital region and the right side of the neck. When raised to a sitting position he leaned heavily backwards, placing his hands on the bed behind him in order to support himself, but he would have fallen backwards unless held up. When placed on his feet he was unable to stand alone, owing to the inclination backwards. He could walk in short steps when strongly supported behind. The gait was not ataxic. There was marked convergent strabismus. From time to time he exhibited a sort of twitching movement of the eyes

outwards, followed at once by a return to the convergent position. Movement outwards of the left eye seemed perfect, but the right eye never got beyond the mid position. Apparently there was paresis of the right external rectus coupled with spasm of both internal recti. This interfered with accurate investigation of other ocular movements, but the upward movements of the globes also appeared to be defective. There was no ptosis. The pupils were moderately dilated, the left being larger than the right. The right pupil reacted moderately to accommodation but doubtfully to light; reaction to either was doubtful in the left. Most intense optic neuritis was present in both discs. Beyond the paresis of the right external rectus there was no paralysis of any part of the muscular system. He would shut his eyes, show his teeth, and put out his tongue when asked to do so. There was no deviation of the tongue. The hand grasp was equal on both sides, though somewhat feeble. The right hand and arm were tremulous; he moved the limb vaguely about, at times seeming to grasp at some object in the air, then placing his hand on his right temple, interfering, as if unconsciously, with ophthalmoscopic examination. He would touch various parts of his face with fair precision when told to do so. He moved his legs freely in bed, but only at request. Deglutition was slow but perfect. Unless attended at regular intervals he had incontinence of urine. The bowels acted only after the use of enemata. The urine contained no albumen. The heart and lungs were sound. The pulse was regular and of good volume, but slow (52 to 60 per minute). The respiration was regular and deep (15 to 16 per minute). The temperature remained between 97° and 98° F. There was complete absence of the knee-jerks on both sides. The superficial reflexes, cremasteric and abdominal, were exaggerated. On tickling the soles of his feet the legs were drawn up spasmodically. He lay in a dazed, semi-conscious state, from which he could be roused for a time to answer simple questions, put out his tongue, and so forth; but his attention soon seemed to wander and was difficult to regain. His speech was slow but quite distinct. He would pause for several seconds before answering a question, but would eventually answer correctly and to the point; if more than a few questions at a time were asked, however, he would cease to reply. Occasionally he spoke of his own accord, and once when a conversation arose in the ward on a recent exhibition he said "I've been there." Asked if it was worth seeing, he replied with emphasis, "I believe you," but nothing further could be elicited from him on the subject. He noticed correctly that the ward clock struck an hour slow. When asked to build a piano for the ward he said, "You've no room for it." He recognised the smell of roast beef, and objected to the mutton on the ground that it was too rich. He read the time correctly from a watch held a yard before his eyes, but would not name various common articles shown to him. More accurate investigation of the special senses was impossible. Sensation to touch and pain, as far as could be ascertained, was normal; he winced when the heat test was tried, but would not say whether he felt hot or cold. Examination of the right auditory meatus showed signs of past catarrh, with thickening and opacity of the tympanic membrane, but no perforation.

The general symptoms were obviously those of cerebral compression. Of localising symptoms, the morbid tendency to fall backwards and the inclination of the head to the right (which afterwards varied, the head being sometimes equally strongly diverted to the left) suggested a cerebellar lesion; while the tenderness of the right occiput pointed to the right cerebellum as the most likely site of disease. The diagnosis rested between tumour and abscess of the cerebellum, causing general pressure. The balance was slightly in favour of abscess, owing to the history of past aural disease. But the affection had been trivial, and the signs of its existence were few. There was no perforation of the membrane, no history of persistent discharge, and there had been no rigors. No history of syphilis could be obtained, and no signs of its presence were found; but on the chance that his condition might be due to gumma it was decided to treat him with increasing doses of iodide of potassium. During the next four weeks his condition remained practically unaltered, except that he wasted rapidly. The temperature was almost persistently subnormal, varying between 97° and 98°, but at times rising one point above normal. The pulse rate averaged between 60 and 70 per minute. He never vomited after admission. His appetite remained good. Mastication was slow and imperfect, accompanied by little or no lateral movement of the jaws. Deglutition was

unimpaired. At the suggestion of Dr. Althaus, who kindly saw the patient on Oct. 12th, strong counter-irritation by means of tartar emetic ointment was applied to the right occiput until active inflammation of the scalp was produced. This caused a rise of temperature of from one to two degrees above normal, but no beneficial effect was produced. On Nov. 1st, at Dr. Hughes Bennett's suggestion, it was decided to trephine, the operation being performed on the following day by Mr. Pearce Gould.

A trephine opening was made behind the right ear so as to expose the right hemisphere of the cerebellum. As nothing was found either superficially or on probing, the opening was enlarged anteriorly and the posterior part of the cerebrum brought to view. Here, again, there was no evidence of any localised morbid condition. The patient recovered temporarily from the effects of the operation, but remained dull and apathetic, and death ensued on Nov. 8th, 1893.

Necropsy.—There was a slight milkiness of the cortical pia arachnoid, with increase of the cerebro-spinal fluid and matting of the membranes over the base. On opening the brain there were noticed considerable dilatation of both lateral ventricles and excess of the ventricular fluid. A hard, somewhat nodular swelling occupied the position of the quadrigeminal bodies, and extended into the left optic thalamus. The optic thalami, quadrigeminal region, and pons were prepared for minute investigation. This examination showed that the tumour extended from the junction of the posterior and middle thirds of the left optic thalamus as far back as the posterior border of the testes. It involved the posterior part of the left optic thalamus and merely pressed upon, without implicating, the right thalamus. It destroyed both anterior and posterior corpora quadrigemina, the right bodies being less implicated than the left. It invaded the grey matter around the Sylvian aqueduct, and passed up to and involved the dorso-mesial part of the sub-thalamic region on the left side only. The tegmentum pontis et cruris was unaffected. The left lateral fillet, in its course to the left testis, was involved by the tumour. Histologically the tumour was an angio-sarcoma of apparently rapid growth.

Remarks.—The two outstanding features of tumour of the corpora quadrigemina are an unsteady gait and oculo-motor paralysis. The former is usually described as being that of a drunken person, resembling the gait of cerebellar disease rather than the heel walk of the ataxic. As the disease advances walking becomes impossible without support. Even in the later stages, however, there is no loss of power, unless from extension of the disease the motor tracts in the cerebral peduncles are involved either directly or from pressure. The oculo-motor palsy consists rather of symptoms in the region of the third and fourth nerves than in that of the sixth, which, indeed, is not unnatural, considering that the position of the abducens nucleus is some distance posterior to the testes. Paralysis of convergence, ptosis, and loss of the upward movement of the globes are the chief phenomena noted in the cases of this disease. Apart from these two symptoms, we would call attention to the fact that vision is not materially altered, except by the condition of optic neuritis, which is a constant feature in the cases. This supports the dictum of Nothnagel: "that visual acuity may be unimpaired in these cases may be stated without fear of contradiction." The difficulty of testing audition in these cases is very great, owing to the mental apathy and listlessness commonly present. It would seem, however, from a review of the cases in which this was carefully tested, that hearing is impaired on the side opposite the lesion, or in bilateral cases on the side opposite that which is most affected. Tremors, chiefly of the arms on voluntary movement, have been observed in other cases as well as in our own. They have been described as similar to those met with in disseminated sclerosis. They are probably due to an extension of the tumour growth into the tegmentum and optic thalamus. The knee-jerks are as a rule exaggerated in these cases; but, as not infrequently occurs in cerebellar disease, they may be abolished even from an early date, as happened in the case here recorded.

FITS FOLLOWING TOUCHING THE HEAD.—A CASE
PUBLISHED BY DR. DUNSMURE (1874).

I RECORDED¹ the case of a boy who had what I thought to be fits analogous to those artificially produced in guinea-pigs by Brown-Séquard's well-known methods. The boy fell down and had certain symptoms to be presently mentioned when his head was touched. A discussion followed the reading of the paper, in which Dr. Hadden, Dr. Hughes Bennett, Dr. Ewart, Mr. R. W. Parker, Dr. Beevor, Mr. Brudenell Carter, and Mr. Victor Horsley took part. I find that Dr. James Dunsmure, so long before as 1874,² published a case in all essential respects like that of my patient. Dr. Dunsmure has been so good as to give me particulars of his patient subsequent to 1874. I have no knowledge of the progress of my patient since the time of publication of his case.

Dr. Dunsmure's patient was five years of age (I refer to the boy's condition in 1874, until I mention his later progress). He began at the age of two years and a half to have attacks when his head was touched, and continued to be subject to them; they increased in frequency and severity, lasted about five minutes, when perfect recovery took place. He did not lose consciousness in them. (*Vide infra.*) Three months ago he was noticed to lose power in the right arm and leg during the attack. He could not speak except that he could say a few words with "o" in them, as "horse," which he calls "oss," "open," "ope." Yet he understood any word that was said to him. "He hums several Scotch airs very correctly, and is very fond of music." Dr. Dunsmure writes further (I italicise some words):—"On touching any part of his head sharply when he is unaware of it, he immediately falls to the ground, perfectly powerless, though quite sensible, and remains lying for a minute or more till he is able to rise again. The first time I saw him, the muscles of the right arm and leg were slightly tonically convulsed; but that is the only time I ever noticed any approach to a convulsion. His mother told me that once or twice, when he had had a very severe fall on a day when he was particularly sensitive to attacks, she noticed slight tremor of the right arm or leg, or of both legs alone. During an attack he occasionally cries; the eyes are either half-shut or open, the pupils are unaffected; the face is generally flushed, but it sometimes becomes very pale a short time afterwards, and the arms fall to the side. The sphincters are never relaxed. On days when he has had a number of attacks, the hands are very unsteady, and shake a good deal. He has a tendency to fall to the left side; sometimes the right arm and leg are quite powerless, and remain so for a minute or more, and then recover, while he generally raises the affected arm up with his left hand. Within the last three months he has used the left hand more than the right for doing anything, as feeding himself, &c., &c."

"It is not necessary for a second party to touch the head to induce an attack, for he frequently causes himself to fall while playing with a piece of paper or a ball, if it happens to come in contact with any part of the head; or even when touched suddenly with his own hands, or in feeding himself, if the spoon comes against his face. Combing his hair is a frequent cause of an attack. On being made aware his head is to be touched, he is able to withstand the attack even if a severe knock is given. He is generally in the greatest spirits, playing and romping about with other children; but some days he is irritable and dull, and on those days he is particularly subject to attacks. On the posterior part of the head there are generally one or two swellings, due to the falls he receives. Tapping him over the spine, especially in the dorsal region, causes him to start, and the right arm is jerked slightly away from the body. While eating anything hard he sometimes falls; for example, if given a lozenge or a bit of

¹ Transactions of the Medical Society, vol. x., 1887.

² Edin. Med. Jour., October, 1874.

sugar, he bites it very cautiously, evidently afraid of it breaking, which, if it does suddenly, he either starts or falls down.

"Galvanism applied to the head produces no attack, nor does the sudden application of heat or cold. Any sudden noise has no effect. When his head is touched during sleep, his whole body starts violently, and in about a minute or less his face becomes paler, which appears to me to be very much the same phenomenon as is produced when he is awake, only he is in the recumbent position, and is not able to fall. He drags his right leg very slightly on walking, and on going upstairs he always puts the left one up first. The digestive system is in good order; tongue moist and clean; urine normal; heart and lungs quite healthy; pulse 100; temperature 98.4°. Dr. Argyll Robertson kindly examined the eyes for me with the ophthalmoscope, and found them quite healthy. During the last six months he has improved very much, the attacks are neither so numerous nor so long. At present they rarely last above a minute.

"It is extremely difficult to know whether there is at the time of fall a momentary loss of consciousness or not. If attacks have been induced when he is sitting, I have noticed his head falls forward for a second, and then immediately recovers itself, during which time he may have been unconscious, or the falling forward of his head may have been entirely due to the loss of voluntary power."

Dr. Dunsmure brought the case before the Edinburgh Medico-Chirurgical Society a few years later. He has obligingly given me by letter particulars of the boy's progress since 1874. Before giving these further details I will remark on the resemblances of my patient's case to that Dr. Dunsmure had previously recorded.

In both cases the patients did not fall when touched on the head if they were aware that they were to be touched. In both cases attacks were producible during sleep. In both attacks were produced by accidental contacts during play, &c. In both there were one-sided symptoms, right in Dr. Dunsmure's patient, left in my patient. In my patient during the attacks, or soon after at least, the eyes turned to the right (evidence, I think, considering that the left limbs were affected, that the attacks were ponto-bulbar, "lowest level," fits) and there was stoppage of respiration for a few seconds. It was not certain that in either case there was loss of consciousness in the seizure. I thought there was in my patient's attacks and Dr. Dunsmure thinks there may have been in his patient's attacks.

I now give the further particulars with which Dr. Dunsmure has supplied me, as to his patient's progress in and subsequently to 1874. It will be seen that the patient had epileptic fits as well as the slighter seizures which for distinction are called "falls."

"During the summer of 1874 the 'falls' were incessant owing to his having been taken out in the hot weather, but they diminished when he was kept in the house. He had to be confined to bed the next summer for a short time, owing to the heat and the frequency of the falls. On March 5th, 1876, he had a nocturnal epileptic fit, and another in a month. After the fits began the 'falls' diminished till August, when the weather was hot, they were so frequent he had again to be confined to bed. He had only one fit to Sept. 11th. From then to Oct. 12th, 1876, he had only one fall and four fits of shorter duration; his right side was paralysed for a short time after each of them, the arm hanging by the side. He had a good many fits and no falls till January, 1877, when he had a bad fit in the morning and six falls in the first fortnight of that month. He had several fits to March, in which he would awake screaming out that he is falling and the mother fancied that, by giving him a slap on the back if she was in time, it stopped the fit. He was put on large doses, twenty-five grains, of bromide three times daily and he had only one fit for many months. In February, 1878, his mother drew my attention to the fact that when his attention was directed to something else and on his then getting a sharp blow on the back his right arm lost power for a minute or two. I saw this; the power returned in about two minutes. On the 31st I saw him again, and his mother stated that on the 20th, when going down the stair, a girl struck him on the back a severe blow with a stick. He ran back to the house and took a fit which lasted five minutes.

"In January, 1880, he had a fit which lasted ten minutes, the right side of the body was paralysed for a quarter of an hour afterwards. For a year or so afterwards fits were brought on by blows on the back. When he had bromide in large doses regularly he was always much better and was

often for months without fits. I do not think there is anything more to say in the case, for after the regular development of epilepsy I did not see much of the case after I made my last communication to the Society till his death.

"The patient died of peritonitis, 1892. The brain was examined by Dr. Bruce, Pathologist to the Royal Infirmary.

"There was no change or disease in the pons or medulla or in any part of the brain, except the cortex. The grey matter was somewhat sodden in appearance and many of the cells were vacuolated."

A SUCCESSFUL CASE OF PARACENTESIS PERICARDII.¹

BY PERCY KIDD, M.D. OXON., F.R.C.P. LOND.,

PHYSICIAN TO THE BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, AND ASSISTANT PHYSICIAN TO THE LONDON HOSPITAL.

A MAN aged thirty-four years, married, came to the out-patient department of the Brompton Hospital on June 6th, 1894, and was admitted by my colleague, Dr. Habershon, under my care, on account of severe dyspnoea. On admission there was extreme dyspnoea, both respiratory and expiratory. The face was pale, ashy, and bedewed with a cold clammy sweat. The expression was anxious. A superficial and rapid examination revealed the presence of a pulse of high tension, and hypertrophy and dilatation of the left ventricle. There was oedema of the bases of the lungs, without signs of general bronchitis, and a small pleural effusion on the right side. The urine contained a small quantity of albumen. The case was regarded as one of granular kidney with asthma probably of uramic origin. A hypodermic injection of a quarter of a grain of morphia was at once given, and in about twenty minutes the dyspnoea had almost disappeared and the patient expressed himself as feeling fairly comfortable. He was then ordered to take liquor trinitrini, one minim, every four hours. Under this treatment he continued to improve. Occasional asthmatic attacks were successfully treated by inhalations of amyl nitrite. As soon as his condition permitted the following note was taken. "Family history unimportant. Previous history: Painter's colic in 1884, and an attack of hæmoptysis in 1889. Ailing three years with cough and occasional hæmoptysis. Present illness began at Christmas, 1893, with hæmoptysis, followed by recurring attacks of paroxysmal dyspnoea. The patient is pale and is still somewhat dyspnoeic. Maintains a sitting or semi-recumbent position day and night. Pulse 98, of medium size, regular tension much increased, artery hard. Heart apex beat at lower border of sixth rib half an inch external to the nipple line. Impulse forcible and diffused. Dulness begins at the fourth rib on the left side and extends outwards to the position of the apex beat. To the right the cardiac dulness merges in the pleural dulness to be subsequently described. Cardiac rhythm cantering, the first of the three sounds heard corresponding with the carotid pulse. Aortic second sound much accentuated. Lungs: On the right side in front dulness from the fourth rib downwards and behind from the angle of the scapula to the base. Over the dull area breath sounds weak and vocal fremitus diminished. At both posterior bases scanty subcrepitant râles. Breath sounds over left lung and upper part of right vesicular and loud. No rhonchi. Urine pale, acid; sp. gr., 1010; albumen, one-tenth; no casts. Ophthalmoscopic examination: Numerous small glistening white patches in the retina on each side external to the discs in the neighbourhood of the macula. Marked whitish thickening of the coats of the retinal vessels."

For the next fortnight there was little change. Asthmatic attacks were relieved by amyl nitrite as a rule, but occasionally a hypodermic injection of morphia had to be administered.—July 22nd: Dyspnoea has been increasing the last few days. The legs are now somewhat swollen and the signs of pleural effusion on the right side have increased. Paracentesis of the right pleura was performed, and sixty-three ounces of rose-coloured fluid were removed. Great relief was obtained, the dyspnoea diminished, and the oedema of the legs almost disappeared.—July 12th: Paracentesis had to be performed again as further effusion into the right pleura had occurred. On this occasion

¹ A paper read before the Medical Society of London on Jan. 28th, 1895.

forty ounces were withdrawn, the fluid showing the same sanguineous character as before. Again great relief was experienced, and for the first time the cantering action of the heart was replaced by the normal rhythm, the first sound being short, the second sound accentuated generally. After about a week the old symptoms returned, and on July 26th the patient complained of severe pain in the left side and was much distressed. A double pericardial friction sound was now heard over the whole præcordia, loudest over the right ventricle. Six leeches were applied to the cardiac region and speedy relief was obtained. A saline mixture containing ten minims of the tincture of digitalis and of the tincture of *nux vomica*, with three minims of liquor trinitrini, was now ordered to be given every four hours. Temporary relief to the dyspnoea was experienced, but the patient vomited occasionally—a symptom attributed to the digitalis. On Aug. 6th the patient had a sudden attack of dyspnoea and cardiac failure. He became pale and faint and his pulse was found to be very irregular and weak. After the administration of a hypodermic injection of ether and of brandy internally he rallied, but complained much of pain in the præcordial region and epigastrium. At bedtime an injection of one-eighth of a grain of morphia was given and the patient slept for a few hours. The next day the following note was made. "Dyspnoea marked. Respiration 32, shallow. Lungs: On the right side dullness reaches in front up to the third rib, and behind nearly to the spine of the scapula. Over the dull area weak breath sounds and diminished vocal fremitus. At the left posterior base slight dullness as high as the angle of the scapula, weak breath sounds, and some creaking. Heart: (Edema of the skin in the cardiac region, extending outwards nearly as far as the nipple on each side. Tenderness on pressure in this situation. Heart's impulse impalpable except at the apex, where it is fairly distinct. Apex beat in the same position as before—i.e., in the sixth intercostal space half an inch external to the nipple line. Cardiac dullness begins at the third rib on the left side, extending outwards and downwards as far as the apex beat. To the right the dullness is continuous with that already described in the examination of the lungs. Heart sounds very feeble; at the apex a cantering rhythm can be recognised; no pericardial friction. Liver much enlarged. Slight ascites. Urine: sp. gr. 1010; contains a trace of albumen. The excretion of urine had fallen during the last three days to twenty-seven ounces." The mixture containing digitalis was now discontinued and ten minims of tincture of *strophanthus* were ordered every four hours. It being now evident that the patient had pericardial effusion, instructions were given to perform paracentesis pericardii if his condition should become worse. The same evening the patient became very restless, the respiration was more laboured, and the pulse weaker. Accordingly at 9.30 P.M. paracentesis pericardii was performed by the house physician, Mr. R. M. Smyth, in the absence of the resident medical officer. A small quantity of cocaine was injected under the skin in the cardiac region, and shortly afterwards a trocar and cannula connected with an aspirating syringe were inserted through a small skin incision in the fourth left intercostal space, as close as possible to the edge of the sternum. The trocar hitched on the edge of the sternum, and after some little difficulty was carefully pushed through the intercostal space until it was felt to be in a cavity. The trocar was then withdrawn and the cannula was now felt to be lifted with each beat of the heart. A quantity of blood-stained serum was syphoned over through the exit tube of the syringe into a porringer. The cannula was gently moved about and the piston drawn out so as to obtain suction. Then fluid of a deeper red colour was obtained, but the cannula soon became blocked, so it was withdrawn and the wound covered with lint soaked in collodion. The patient was relieved at once, the pulse became stronger, and the apex beat of the heart came half an inch lower down than before. Five ounces of fluid were removed. On standing a layer of blood was deposited, the supernatant fluid presenting a clear claret colour.—Aug. 8th: The patient had a good night; he is less restless and in less pain. Respiration 30. The oedema of the chest wall has diminished. Pulse 120, stronger and regular. During the day the pulse-rate varied from 120 to 60, but in the evening it resumed its old rate, 120. The amount of urine passed in the twenty-four hours following the tapping rose to fifty-five ounces.—Aug. 9th: Fair night. Pulse 120, irregular. Cardiac dullness reaches up to the third rib. Rhythm cantering. Respiration 32. Urine, sp. gr.

1010. Albumen one-tenth.—Aug. 10th: The patient seems weaker. Pulse 80, very irregular. *Strophanthus* had to be discontinued on account of the vomiting it seemed to excite. A hypodermic injection of one-fortieth of a grain of strychnine was given in the morning. At 3.30 P.M. I saw the patient. He was then very dyspnoic and distressed. The respiration was 30. The pulse was 90, tension being lower than formerly. Intermissions, mostly coinciding with inspiration, occurred every sixth or seventh beat. The physical signs were unchanged. It was determined to resort to paracentesis again, the operation being performed by the resident medical officer, Dr. Stanley Ballance. The patient was placed slightly on the left side in a semi-recumbent position. After freezing the skin with ice and salt a small incision was made in the fifth intercostal space on the left side two inches from the sternum, and the trocar and cannula were then inserted. After slight aspiration had been employed the fluid was allowed to syphon over into a glass vessel, twenty-eight ounces being collected. The fluid had almost the colour of pure blood, and on standing some coagulation occurred. The specific gravity of the fluid was 1020. During the operation the patient was given a small quantity of brandy-and-water to sip frequently. After the fluid was withdrawn he expressed himself as feeling much easier. His colour improved, the pulse became stronger and less irregular, and the dyspnoea was obviously relieved. The area of cardiac dullness was not perceptibly diminished. On Aug. 11th the patient slept well in the recumbent position, which he had not been able to assume before. The oedema of the chest wall was less. The pulse was 88, stronger, but still irregular. The heart sounds were distinct at the apex, but fainter at the base; impulse was stronger. The quantity of urine excreted during the twenty-four hours following the operation rose to ninety-seven ounces. For the next month the improvement was maintained, though attacks of dyspnoea recurred from time to time. On Aug. 17th the cantering rhythm of the heart returned, the second of the three sounds now coinciding with the carotid pulse. The pulse became regular and regained its high tension. The ophthalmoscopic appearances underwent no further change. The physical signs in the chest remained the same. After the second tapping the patient was given a mixture containing iron and *nux vomica*. From the second week of September, when I went for my holidays, my colleague, Dr. Habershon, kindly took charge of the case. On Sept. 15th the patient's condition changed for the worse. The pulse became weaker, the dyspnoea increased, and the quantity of urine had fallen in two days from eighty-eight ounces to forty-eight ounces. The urine now contained one-fourth albumen, the sp. gr. remaining at 1010. As the area of cardiac dullness was thought to have increased slightly it was decided to tap the pericardium again. Paracentesis was performed in the fifth intercostal space on the left side just internal to the situation of the second puncture. No fluid could be obtained. From this time the patient gradually failed, the tension of the pulse fell, the restlessness and respiratory distress became greater, and the quantity of urine steadily declined. Frequent injections of morphia were required to relieve the distressing dyspnoea, but the patient sank and died quietly on Sept. 22nd, six weeks after the second tapping, consciousness being preserved to the last.

Necropsy.—There were recent pleuritic adhesions on both sides; the left pleura was adherent to the pericardium. The pericardial sac was entirely obliterated by adhesions, firm at the base but very soft towards the apex and lower part of the right ventricle. The pericardium was studded with numerous small hæmorrhages, old and recent. The heart (weight with pericardium twenty-three ounces) was greatly enlarged, the left ventricle being mainly affected, and its walls measuring nearly one inch in thickness. The muscle was rather soft. The cavity was moderately dilated. The valves were normal. The lungs were oedematous. There was slight marginal emphysema. There was no trace of tubercle. The larynx was oedematous. The kidneys (weight seven ounces and a half) were much contracted. The capsules were slightly thickened but stripped easily, leaving a granular surface. There were a few small cysts and some yellowish patches in the cortex, which was greatly thinned.

Remarks.—I have ventured to describe this case as a successful one for the reason that marked and immediate relief was obtained from paracentesis, and the improvement was maintained for fully four weeks, the patient's death being the inevitable result of advanced renal disease. Post-mortem examination showed that the pericardial cavity had been closed by adhesions. The case was, it will be admitted,

a very severe one—granular kidney with uræmic asthma, cardiac dilatation, retinitis, and sanguineous effusion into the pleura and pericardium. The fact that paracentesis pericardii gave unmistakable relief in so desperate a case is the best testimony to the efficacy of this mode of treatment. All who saw the case—and they were many—were convinced that but for the tapping the patient could not have lived many days. The first tapping, performed in the fourth left intercostal space close to the sternum, though it gave temporary relief only yielded five ounces of fluid. Accordingly on the next occasion the puncture was made in the fifth space two inches from the sternum. Dieulafoy recommends that the trocar be introduced at no great distance from the sternum, so as to avoid opening the pleura, but there was thought to be little danger of this occurrence in the present case as there were good reasons for believing that the pleura and pericardium were adherent. The greater success of the second paracentesis is largely to be attributed to the semi-erect position of the patient at the operation facilitating the displacement forward of the exudation, which, as so often happens, had gravitated to the posterior part of the pericardial sac behind the heart. The hæmorrhagic character of the fluid withdrawn from the pericardium as well as from the pleura is noteworthy, as pointing to the severity of the renal affection. The quantity of fluid removed on the second occasion, twenty-eight ounces, is rather large as compared with the average of cases recorded, though a much larger quantity has been removed in individual cases. It is, however, well to remember that the removal of a much smaller amount—e.g., four or five ounces—has been productive of excellent results in several cases that have been reported. The good effects of the tapping were manifested by the circulation, respiration, and secretion of urine. The rapid relief of the dyspnoea shows that this symptom was largely due to the mechanical difficulties under which the heart was labouring. Not less remarkable is the rise in the amount of urine that occurred. Thus, in the twenty-four hours preceding the first operation the quantity was twenty-seven ounces; during the next twenty-four hours fifty-five ounces were passed. After the second operation, on Aug. 10th, ninety-seven ounces were measured, and ten days later the quantity had risen to 137 ounces. No digitals, strophanthus, or other diuretics were given after Aug. 9th, so that the diuresis can only be attributed to the improvement in the circulation brought about by paracentesis. The oedema of the skin in the præcordial region began to diminish as soon as the pericardial pressure was relieved, but it was some days before it had completely disappeared. The diagnosis of the pericardial effusion presented no difficulty. Although the pulsus paradoxus was not present in its typical form it was noted on the day of the second tapping that the intermissions of the pulse mostly coincided with inspiration. This condition could no longer be observed after the fluid had been removed, and it did not return. The repeated hæmoptysis that occurred early in the history of the case is worthy of note in connexion with the hæmorrhagic character of the effusions into the serous cavities, and with the fact that the necropsy revealed no disease of the lungs with the exception of slight marginal emphysema. I have met with several cases of pulmonary hæmorrhage in middle-aged and elderly people who were free from any sign of cardiac or pulmonary disease beyond slight emphysema, but in whom the existence of granular kidney in a latent form was highly probable. Referring to these cases in the discussion that took place at the Medical Society of London a few years ago on the late Sir Andrew Clark's paper on the Non-tuberculous and Non-cardiac Hæmoptysis of Elderly Persons, I ventured to attribute the hæmorrhage to a rise of pressure in the pulmonary circulation secondary to the high tension in the aortic system. When, as is usually the case in such circumstances, some degree of emphysema and general arterial degeneration coexist we must recognise the presence of conditions favourable to the production of pulmonary hæmorrhage. I still regard this explanation as simpler and more probable than Sir Andrew Clark's assumption of a specific lesion of the pulmonary arterioles and capillaries dependent on "the arthritic diathesis." In a valuable paper by Dr. Samuel West on a case of Punctured Pericarditis treated by Paracentesis and by Free Incision, with Recovery,² statistics of paracentesis pericardii

are included, and many interesting points are brought out. Since this paper was published other cases have been recorded; but as Dr. West's conclusions still seem to comprise all the essential points I will now quote them in conclusion: (1) Paracentesis pericardii is not only justifiable, but an operation which may be safely undertaken with ordinary precautions; (2) the most suitable place for puncture is, in ordinary cases, in the fifth left intercostal space one inch from the edge of the sternum; but if the pleura be adherent the puncture may be made safely much further out, and even in the sixth space; (3) the instrument employed should be a trocar and cannula, with or without aspiration; and (4) the operation may be performed with advantage, not only in the pericardial effusions of rheumatic or primary origin, but also in those which occur in the later stages of general dropsy, if it should appear that the fluid in the pericardium is adding to the difficulties under which the heart is placed.

THE DIFFICULTIES OF PROGNOSIS IN INSANITY.¹

By HENRY SUTHERLAND, M.D. OXON.

EVERY practitioner of medicine is aware how difficult it often is to give a prognosis in ordinary cases of bodily disease. There is no point in our professional career which is so likely to endanger the opinion the public may have formed of our skill in diagnosis and treatment. It can, therefore, be easily understood that in all cases of mental disease this difficulty becomes much augmented, for the reasons that the patient will not assist us by describing his subjective symptoms, and will frequently complain that he is suffering from various bodily complaints of which there are no signs whatever. In forming an opinion about any given case of bodily disease we are usually asked: "Will the patient recover?" "How long will he be ill?" "Will the patient die?" "If so, how long has he to live?" And, of course, such questions as these refer just as much to the somatic troubles which may accompany mental disease; but in the prognosis of insanity we have to answer in addition the following style of questions: "Will the patient recover *mental* health?" "If so, how soon?" "Will he die of the *mental* disease?" "If he recovers, will he have another attack?" "If he remains permanently insane, will his life be a long or a short one?" The classifications which have been made of mental diseases do not throw much light on the subject of prognosis. Greissinger divides them under two heads—curable with functional disorder of the brain and incurable with organic disease. Maudsley drops an excellent practical hint in his subdivisions into emotional and intellectual insanity, emotional insanity being a condition in which horrible crimes are committed, while at the same time the public are unable to detect any abnormality in the intellectual faculties. But to my mind the rule of thumb employed at St. Luke's Hospital is by far the best foundation upon which we can rely for a really useful division of the subject. At this hospital curable cases are alone admitted. The medical officer is instructed to ask the friends who are applying for the admission of a patient: "What is his age? What is the duration of the attack? Is it the first attack or not?" and, lastly, "What is the form of mental disorder from which the patient is suffering?" One of the most important points in regard to prognosis is undoubtedly the age of the patient. Thurnam tells us in his statistics that "the probability of recovery is greatest in the young, and undergoes a regular diminution as age advances." Most writers look upon an attack occurring after the age of fifty as hopeless. Bearing this point in mind I gave a guarded but unfavourable prognosis in the case of a Member of Parliament aged fifty years who consulted me some years ago. His grandmother had committed suicide and his father had died insane. The patient had what he called "une idée fixe," a sort of modified delusion, with other well-marked mental symptoms. I certainly believed his case to be incurable. I prescribed rest, and I attended to his liver, which was much enlarged. Three months later he had completely recovered, and was able to make a long speech in the House of Commons. I must confess I was completely

² Transactions of the Royal Medical and Chirurgical Society, vol. xlvii, 1883.

¹ A paper read before the West London Medico-Chirurgical Society.

deceived on that occasion, as from the history of the case I had every reason to believe it to be incurable. As a contrast I may allude to the following case. A youth aged eighteen years was brought to me some time ago who was said to be a victim of self abuse. The late Dr. William Wood, who had a more profound knowledge of insanity than anyone I ever met with, pronounced the case to be hopeless. I did not agree with him; but I was wrong. In the course of time the patient so far recovered as to be able to start on a sea voyage. But the first night at sea he told his attendant that a horse had put his head in at the cabin window. After this he became violent, was placed in irons, sent home, and placed in an asylum. He is now under my care, having been insane for more than twenty years without any lucid interval. My opinion that his youth would save him from being a chronic lunatic turned out to be incorrect. The number of attacks a patient has had seriously affects the prognosis. A woman at the change of life consulted me. She had become depressed in consequence of having been left a large fortune unexpectedly, became suicidal, was sent to an asylum, and recovered. I prophesied that she would be a victim to recurrent melancholia. She went out and tried to keep house, but had not the strength to do so. She had a second attack and recovered. The patient went out again and got into the hands of two drunken women who swindled her. She had a third attack and returned to the asylum. She again left, and was taken in hand by another woman, and has had several attacks since. During one of them her brother and I endeavoured to persuade her to become a 'chancery patient.' She refused to take our advice, and she is now gradually drifting from a state of melancholia into one of hopeless dementia. On this occasion I was right. But in a case later I was not so fortunate. A woman had six times suffered from puerperal insanity and had been received into an asylum. When her seventh child was being thought of I advised that she should place herself under medical supervision as a boarder, and thus avoid the fatigues of the London season at this critical period. She passed through her seventh confinement without an attack. She had an attack on the birth of an eighth child. After that she was absent from her husband for two years, but after one year's absence from him a ninth child was born; a divorce was the consequence. Since then she has had children, and has remained perfectly sane on each occasion. My idea that she would end in chronic dementia has thus far proved incorrect.

The form of insanity is also of the greatest importance in giving an opinion. In Dr. Hack Tuke's Dictionary of Psychological Medicine there is an excellent article by Dr. Blandford giving the probability of recovery in every form of insanity. It can only be remarked here that acute cases as a rule are curable and that chronic cases are incurable. According to a very clever classification of mental diseases, drawn up by a committee of the Medico-Psychological Association, the following forms are incurable: general paralysis, epileptic insanity, senile insanity, paralytic insanity, and perhaps idiocy. In Dr. Mickle's work on General Paralysis of the Insane he mentions the names of not less than thirty-six writers who have published cases of recovery from general paralysis. In my own opinion a recovery from general paralysis, when the symptoms are well marked, never has and never will take place. In such so called recoveries either a wrong diagnosis has been made or the patient has left the asylum during a temporary convalescence and has been lost sight of. In the advanced stage the diagnosis of this disease is generally very easy. At least, so I and some others thought about a man whose case at the time attracted much attention in the psychological world. This patient's left pupil was always much contracted and insensible to the stimulus of light. The right pupil was much dilated. He had marked hesitation in his speech, more especially in his pronunciation of linguals and labials, which, as everybody knows, is very characteristic. I remember his delusions of grandeur very well. He said he had a horse which was going to win the Derby, that he was about to row for and win the Diamond Sculls, and that he had bought a four-in-hand. The case was carefully watched, epileptic attacks and other signs of advancing disease being daily anticipated. At the end of three months the patient made a good recovery, was discharged from the asylum, and I have reason to know never had a second attack. It was found out afterwards that his hesitation in speech was congenital, that the contraction of the left pupil was due to an old iritis, and that the

delusions of grandeur were only those which may be met with any day in certain cases of acute mania.

Any form of insanity associated with epilepsy is generally considered incurable. The exceptions to this rule are infantile convulsions, epileptic insanity at puberty in girls, and epilepsy after a prolonged and excessive use of alcohol. I was once sent down to Wales to rescue a lunatic who was being robbed of his property. He had been staying for some months in a low village inn, where, in order to conciliate him, he was supplied with unlimited beer. I found him reeling about with a glass of beer in his hand, which he sipped all day. I brought him up with great difficulty to London. On his arrival he had three distinct epileptic fits. We all pronounced the patient to be suffering from incurable epileptic insanity. In this we were wrong, as the patient for ten years never had another epileptic attack, the three on admission having been entirely due to drink. About the same time a woman aged twenty-eight years was sent by Dr. Buzzard suffering from epileptic mania. She commenced having these fits at about twenty-five years of age, and they were increasing in frequency every week. The diagnosis was clear and the outlook hopeless. After being in an asylum for some years she died from exhaustion, complicated with bronchitis. On this occasion we were all correct in our opinion.

A word as to idiocy. The prognosis in this form is most unfavourable, but more hopeful than might be supposed. Dr. Shuttleworth tells us that of patients discharged from idiot asylums after full training, 10 per cent. are self-supporting and more than 40 per cent. are capable of performing the ordinary transactions of life. Some years ago I was locum tenens at St. Luke's Hospital. As already stated, no incurable patients are admitted to this institution, and all patients are seen by the committee on their arrival. A male patient was brought into the board-room whose relatives had told us he was suffering from acute dementia. Two other medical men and myself were about to give directions as to the ward in which the case was to be placed, when a layman who had sat for many years on the committee exclaimed, "That is a congenital imbecile." I was sent out of the room to make further inquiries, and I found the layman was right, and that the three medical men, including myself, were wrong in their diagnosis. The patient was not admitted. An infant was brought to me by its parents about sixteen years ago. Forceps had been used at its birth, and the frontal bone had been compressed so that its form resembled the keel of a boat more than anything else. My prognosis was unfavourable. The girl is now eighteen years of age, can only articulate as a child of five years might do, and delights to play with dolls and to read childish books. She is quite incapable of doing any arithmetic or managing her own estate. It is impossible to describe cases illustrating points in prognosis in every variety of insanity, but we may take it for granted that in any patient in whom there is a regular periodicity in the attacks all hopes of cure are at an end. I have a woman under my care at the present time who suffers alternately from mania and dementia, each form of mental disorder lasting as nearly as possible nine weeks. I have also a man similarly affected. In most cases of *folie circulaire* which have come under my notice I have found dementia taking the place of mania more frequently than melancholia. Homicidal insanity is in my experience incurable. I was called upon some years ago to examine a man who had murdered his wife and two boys and also attempted to murder his two other children, but they refused to drink the poison he had prepared for them. The murderer then placed his own head on the line of a railway when an express train was expected, intending to commit suicide. He was rescued from this position by a pointsman. He was very much attached to his wife and the children he had killed, he had a good balance at the bank, and was in a good situation. He gave himself up and confessed all to the police. I had not the slightest doubt that the prisoner was suffering from the form of insanity known as "impulsive," which has been so ably described by Dr. Maudsley, and that he was an incurable lunatic. The judge, however, took a different view, informed the court that he would have no more murderers let loose on the plea of mental derangement, and was pleased to say that I had thrown dust in the eyes of the jury. After retiring for a few minutes the jury returned to the court, their verdict being "Not guilty, on the grounds of insanity." I visited Broadmoor Asylum some years later, where the prisoner had been sent, and found him to be one of the most maniacal homicidal patients in the institution, and also perfectly

incurable. The duration of the attack has naturally a great influence upon the chances of recovery. At the Retreat, York, 80 per cent. recovered who had been treated within the first three months of their attack. During the first year about 60 per cent. recovered. After the first year about 10 per cent. recovered. Dr. Thurnam says: "It may be stated fairly that six times as many cases recover within the first year as recover after the first year of the illness. After two years recovery is rare." Nevertheless, recoveries have been known to take place after six, ten, and even twenty years' duration. A woman was admitted to an asylum suffering from suicidal melancholia. Before she was placed under treatment she had gouged out her right eye with her thumb, in obedience to the command in the Bible, which says, "If thine eye offend thee pluck it out and cast it from thee." After some time the melancholic symptoms disappeared, and she settled down into what we considered to be a state of chronic incurable dementia. At the end of seven years she made a sudden recovery and was discharged perfectly able to manage her own affairs. In a long experience I have never known a case recover after so long a duration as seven years. I have had experience of patients, both male and female, who are still under my care after thirty, forty, and in one case fifty years. It is needless to remark that the prognosis is perfectly easy in such cases. With regard to sex it may be observed that a larger proportion of women than men recover. The numbers are 44 per cent. for females and 36 per cent. for males. One reason for this excess of recoveries on the women's side is that they are less afflicted with general paralysis than are the males.

I will now turn to somatic influences with regard to this subject. In my experience the prognosis in insanity from sunstroke is favourable in mild cases, but most unfavourable in severe cases. Sir Joseph Fayrer tells us that on post-mortem examination after sunstroke the brain and its membranes are found congested. My own idea is that when a person is attacked either slightly or seriously by *coup de soleil* the sympathetic circles of nerve fibres surrounding the arterioles become paralysed permanently, and in consequence the bloodvessels do not contract naturally. Hence a larger amount of blood is conveyed to the brain under even a slight stimulus, and excitement and mania result. I was once at a private ball at a seaside town. A young man entered the room, much flushed and talking loudly. He proceeded to pull the cornet out of the mouth of the player, lifted the hands of the pianist from his instrument, and pushed the violin from under the chin of the fiddler. He was expelled from the house, everyone saying he was drunk. He recovered next day, called on the hostess, and made his apologies in due form. This young man was an officer in the army and had had a slight sunstroke. He was a teetotaler, but feeling tired before the ball he took a glass of wine to revive himself, which went to his head and caused a transitory attack of mania. I had no reason to disbelieve his statement that one glass of wine produced these awkward consequences. But insanity from a severe sunstroke is a very formidable and incurable form of mental disorder. I had for many years an Indian general under my care who was one of the most dangerous patients it has been my lot to deal with. His condition was entirely due to a severe sunstroke he had sustained during an unusually hot summer in India. In such cases I have observed that there is a period of incubation. The symptoms most characteristic of the disease do not appear till some months after the exposure to the solar rays, although perhaps in the meantime a slight intellectual and emotional departure from the healthy standard may be observed. The catastrophe I am about to relate took place during the Indian Mutiny some forty years ago. The general had been told off to guard a certain number of commissariat waggons. His story, which he presented to me most modestly, has neither a clinical nor a pathological interest, but well illustrates how the mind may become unhinged even some months after a sunstroke has visited the patient. He said: "I was in command of a party of forty horsemen. We came suddenly upon a force of 400. It was a case of ten to one. It was my duty to retire, but I felt that murder was in the air. I gave the order to my men to charge. My trumpeter was shot down on the right of me and my orderly on the left of me. I cut my way in and I cut my way out. All perished except myself, and I thought I was well out of it." In these few words were expressed what appeared to me to be a most romantic episode of military life. Unfortunately there is a seamy side to the story. The general was tried by court-martial, and his behaviour was so eccentric on this occasion

that a medical examination as to his state of mind was ordered. He was found insane and sent from India to an asylum, where he remained for twenty years and finally died an incurable lunatic.

I now pass to the prognosis in cases of alcoholic insanity. There is no class of cases which recover so rapidly as do those of acute alcoholic insanity due to one inordinate drinking bout, and there is no class of cases more incurable than that of patients who during a long course of years have soaked themselves day by day in stimulants. A captain in the Royal Artillery was admitted suddenly one afternoon to an asylum. He had indulged in an unusual amount of alcohol and had become mischievous and almost homicidal. He had taken his wife in his arms and had held her over the balcony of his house and threatened to dash her on the spikes of the area railings below. The police were called in, and he was certified and sent to a harbour of refuge. On admission he was in a state of violent mania and passed the night in the padded room. I visited him again next morning, and after a three hours' examination could find no indications whatever of mental aberration. He had completely recovered in one day, the recovery being simply due to abstinence from stimulants. By his own request he was detained as a boarder for a week, as he said, to keep him from the drink. On his discharge he took more freely than ever to alcohol, and died six weeks later from delirium tremens. The prognosis was, however, very different as from even a temporary recovery in the case of a man aged seventy-six years whom I was sent for to attend one Sunday morning. He had for not less than forty years been in the habit of getting drunk frequently, although able to go down to his office in the City and manage his affairs fairly well. At last he became so unrepresentable that his sons were obliged to protest against his taking any further part in the business. The unfortunate part of the case was that the man would neither die nor become insane. In France a *conseil de famille* would have been held to decide what was to be done with this worshipper of Bacchus. Unfortunately no such law obtains in England. I only saw him once, but I heard afterwards that his and his sons' business was going from bad to worse owing to his unfortunate propensities. In this case it was suggested to my mind that the law of China as to the treatment of lunatics might have been justifiably employed. In that enlightened country they have but one method. All lunatics there are treated by decapitation. I have before alluded to Dr. Maudsley's subdivision of mental diseases under the two heads emotional and intellectual insanity. Emotional insanity is a very important form to recognise. It is very rare. It leads to horrible crimes being committed by its victims. The intellect being nearly but not quite intact, it is impossible to persuade the relatives that there is anything wrong with the mind of the patient. The prognosis is usually most unfavourable in this form. I have a woman at present under my care residing in the house of a medical man. She has been insane for about five-and-twenty years. On one occasion a high authority on lunacy visited her and pronounced her to be perfectly sane. I asked him how long he had talked to her. He said ten minutes. I told him to go back and give her ten minutes more. In the course of the second ten minutes all the delusions and hallucinations came out, and he was obliged to confess that she was an incurable lunatic. This patient knows a great deal, but not all, about her investments and dividends, but ask her to describe a carriage accident or any place of amusement she has visited and she breaks down before the end of even a short narration. She indulges in the most filthy conversation, rendering it impossible for her to take her meals with the family. The case is incurable. I had another very curious case under my care a few months ago. The patient was a clerk in a Government office, engaged in the most complicated transactions during many hours of the day. Excess of alcohol was the root of the evil in his case. If he were in the public streets or an omnibus he fancied that people put up their hands to their mouths, stamped their feet, or made grimaces on purpose to annoy him. He had a brother and a wife, one of whom always accompanied him to and from the office. It was useless to tell him that they, who had met the same people in the street that he had, had never seen them do anything which might be construed into an insult. He became worse, and I obtained leave of absence for him for six months. My prognosis was that as long as he kept from drink he would be perfectly sane. He became a teetotaler and recovered perfectly. The extraordinary part of the case was that this man, affected with delusions of suspicion, was able

to carry on severe mental work all the time he was apparently insane. As to delusions generally, it may be said that if the patient has a variety of them, quickly changing and accompanied with noisy violence, the outlook is hopeful. Fixed delusions, existing for more than a year and continuing when the acute symptoms subside, mark the case as incurable. From among such patients we obtain our asylum kings and queens, who are content to work in the scullery or laundry during the day and assume Court dress or a regal crown when festivities take place in the evening; but of all delusions those that are progressive are the worst as regards prognosis. The general paralytic will commence by telling you he is going into Parliament, that he has been knighted, made a baronet, or created a peer, that he is the Prince of Wales, and finally that he is God Almighty Himself. This is an important point to be remembered in diagnosing a case of general paralysis from one of chronic mania. A great deal of light is thrown on prognosis by observing the postures and movements of the insane. I have a young woman at present under my care who sits all day with her arm over the back of a chair and her head leaning on it. This position has remained fixed during the day for three years. The outlook is hopeless. Another woman, young on admission, rabs her nose continually, making it very red. This she has done for many years. A man under my care walks round two flower-beds in the garden, his course taking the shape of the figure 8. He kicks anyone who gets in his way, but is otherwise harmless. One elderly man has for twenty years rolled a pocket handkerchief up in a ball and turned it round and round in his left hand. With his right he continually percusses his knee and thus wears out the cloth of his trousers in less than a week, necessitating endless patches. *Hæmatoma auris* almost always is found amongst chronic incurable cases. I have a woman with a marked swollen ear at present under my charge who will never recover. I have, however, seen *hæmatoma* in sane people, generally prize-fighters. I exhibited a professional boxer at the Clinical Society of London some years ago who had this peculiarity. Certain bodily complications have great influence on the outlook. For instance, the recoveries in puerperal insanity are very numerous, but if the case should be accompanied by albuminuria the patient almost invariably dies. If the patient should increase in weight, the mental condition remaining unaltered, the outlook is very unfavourable. A woman admitted in 1891 weighed 8 st. 13 lb., and on the third anniversary of her admission—that is, in 1894—she had increased in weight to 12 st. 2 lb. This was an increase of 3 st., or 1 st. a year. Her delusions are always the same—that she is suffering from various bodily complaints of which there are no tangible proofs. Syphilitic insanity in the early stage is fairly curable, but later ends in the death of the patient. I had an Indian colonel under my care for many years suffering from syphilitic mania. Not being satisfied with my treatment a very eminent physician was called into consultation. A third medical man, a friend of the patient, was present. The physician diagnosed the case as one of syphilophobia—that is, a delusion on the part of the patient that he has contracted syphilis. I made no remark and the physician departed. When he had left the room I turned up the patient's trousers and showed his friend, the third medical man, a large open brown syphilitic sore which the patient had had on his shin for many years. The patient died a month later. The condition of the blood in the insane is a great guide in giving an opinion as to how long a patient has to live. When I was at the Wakefield Asylum I examined under the microscope the blood of some hundreds of lunatics. The results were very satisfactory. It would take too long to enumerate them here, but I cannot resist mentioning one point which was to me very striking. I found that if, in general paralysis of the insane, a much larger proportion of white corpuscles as compared with the red was present, the patient was sure to die within four days, although he might apparently be in fairly strong health. This and my other observations have been confirmed by Dr. Lauder Lindsay and Dr. Rutherford.

Before concluding, I should like to say a word or two about the diagnosis of recovery in a patient. Recoveries are always calculated on the admissions. According to Dr. Thurnam they may vary from about 25 to 50 per cent.; but, as I have said, at St. Luke's Hospital, where only curable patients are admitted, the number of recoveries reaches 60 per cent. Generally speaking a rapid recovery is likely to be succeeded by a second attack. A slow recovery is much more hopeful.

Convalescence from insanity is indicated by quietness of mind in the patient: he speaks freely about his disease, he does not perpetually bother the physician as to when he is to leave the asylum, he asks to see his friends, and he returns to his usual employments. An outburst of weeping in females during an attack of acute mania is a good sign, as showing that the patient is aware of her condition. On the other hand, a contented state of mind points to increasing dementia. Esquirol remarks that many patients who are considered cured by their relatives are not so really. In this I quite agree. In proof of this I may mention that not less than three patients removed from our care by the wish of friends and contrary to advice committed suicide, one on the very night of his discharge. Patients are frequently sent back to me to be examined after they have left in order to ascertain whether or not they are capable of managing themselves and their affairs. A list of their former delusions is prepared from the case-book, and the patients are taxed with them one by one. The conclusions are drawn from their answers. Valuable information can also be got from the attendant who usually accompanies them as to their actions and habits being sane or insane since they left the asylum. In almost all cases three months after discharge there are still present traces of the old disorder. Frequently the patient looks lost and distressed, the angles of the mouth are drawn down, there is a general feebleness about the outlines of the features, and the bodily health is never quite re-established. They complain of great irritability and they are easily moved to tears. Their letters also eloquently express their undecided and vacillating state of mind. In females there is a weak smile on the face and frequent showing of the gums, the eyebrows are elevated as they speak, and there is a marked transverse corrugation of the forehead expressive of doubt and anxiety. But it is only by long experience and a careful examination of a case that we are able to determine from these rough rules what is to be done with the patient. The importance of giving a correct prognosis in cases of mental disease cannot be over-estimated. Frequently large pecuniary interests depend upon our opinion—as, for instance, when a large sum is offered to the patient if his life is only to be a short one, as in general paralysis, or if he is to receive a pension if his life is to be a long one, as in chronic melancholia. The matrimonial prospects of both sexes are also much affected by the form of insanity and other points which have to be gone into when an alliance of this kind is contemplated. Cases of hysterical mania in young girls are very hopeful, as well as to recovery as to the non-probability of a second attack. Any girl who has had two attacks of insanity ought not to marry in my opinion. The parents of both parties will come to consult us on these difficult and delicate matters. One rule I always lay down in such cases, and that is that the sane contracting party should be told the whole truth about any previous attack from which the other may have suffered, and then if he or she choose to proceed with the engagement they do so with their eyes open and take the responsibility on themselves. The wife of a medical man during her engagement told her future husband that she had some dreadful secret to reveal to him. He thought she referred to some previous engagement. She said to me afterwards, "He little thought I had two asylums at my back," meaning she had been twice certified as a lunatic. Six weeks after marriage she became insane and remained so for many years, the unfortunate husband having all this time to maintain a wife who was worse than dead to him. Finally, our method of arriving at a correct prognosis may be compared to weighing in a pair of scales those points which, on the one hand, are in favour of, and, on the other, are against the chances of recovery in any given case, such points, however, not being estimated by their number, but by their quality. Experience alone can teach us the value of each individual point. But when the importance of the subject is considered it is surely our duty to neglect no opportunity of improving our natural powers of observation, and thus to be enabled by the accuracy of our opinion to confer health and happiness upon our less fortunate brothers and sisters.

Richmond-terrace, Whitehall, S.W.

MEDICAL MAGISTRATE.—Mr. Thos. E. Jacobson, L.R.C.P. Edin., M.R.C.S., has been placed on the Commission of the Peace by virtue of the office of chairman of the Sleaford urban district council.

"FIRST AID IN ELECTRIC ACCIDENTS."

By W. S. HEDLEY, M.D. EDIN.

IN THE LANCET of Aug. 25th, 1894, there appeared an article on "The Pathology and Treatment of Electric Accidents." This was followed, on Sept. 15th, by a letter under the above heading. It was there suggested that the appearance of a short code of plain rules emanating from some authoritative source bearing on the treatment of persons suffering from electric shock would be useful and opportune. In the same letter several expedients were pointed to suitable for dealing with such emergencies. Since that time definite instructions on these points have appeared in various quarters. The *Electrical Review*, after consulting medical opinions, has formulated a set of clear and concise instructions, and the electrical department of the Midland Railway Co. has issued a more elaborate code for the guidance of its own employés. It is now reported that the French Academy of Medicine has been asked by the Minister of Public Works to offer suggestions on these points, with a view to their being formulated into rules by a special technical commission. It is evident that accidents of the kind in question must be regarded from an electrical as well as from a medical standpoint. The purely medical aspect of such cases is simple, and, roughly speaking, resolves itself into the application of d'Arsonval's rule, "Un foudré doit être traité comme un noyé," not forgetting at the same time that syncope, rather than asphyxia, is at times the prominent condition to be dealt with. If, however, the body of the injured person be still in contact with the electric circuit there are in the first instance points of an electrical nature to be considered. Three possible conditions of contact present themselves, one or more of which may exist at the same time: 1. The body by contact with two conductors of different potential may have short circuited the current. Such a contact is usually fatal at once. 2. The body in contact with one conductor may have taken a portion of the current to earth. In this case the gravity of the accident will depend upon the nature of the contacts between the body and the conductor and the body of the earth. 3. The body by being in contact with two points of the same conductor (e.g., by holding with both hands) may have become the seat of a derived or shunt circuit. This, by itself, is the least dangerous form of contact, but of course it becomes much more serious if, at the same time, a circuit be completed to earth through the body. Whatever be the nature of the contact, it is clear that the first thing to do is to stop the dynamo or switch off the current; and if the accident has occurred near the dynamo room or in the vicinity of a switch there will doubtless be someone present who can promptly do so. Failing this, however, no time must be lost, but means at once taken to detach the body of the injured man from the circuit. Here the "First-Aider" must, in self defence, adopt certain precautions, all of which may be summed up in the word insulation—insulation from the cable, insulation from the earth, and insulation from the body of the injured person. This means, in practical language, that the hands of the rescuer must be covered with some hastily improvised insulating material, such as several thicknesses of a dry garment, and he must at the same time stand upon something of the same kind, such as a heap of dry rags or clothing, or a board or dry straw.¹ With these precautions the rescuer may pull the body from contact with the circuit, raising if necessary that portion of the injured man's body which may be in contact with the ground. Whilst this is going forward there are several other expedients available which to the non-electrical mind are perhaps a little perplexing in their nature and variety. Amongst these may be enumerated the diverting of the current to earth by some conductor of low resistance, such as an iron rod or a wire of large capacity, severing the conductor if small enough by a cutting instrument with insulated handles, or if the injured man be actually in contact with both conductors, the current may be short-circuited close to the part touched by the body.

In considering the "lethal" effects of electric currents it is commonly supposed that the alternating current is more dangerous than the constant one. The Board of Trade regulations, as well as the rules of the fire insurance offices, seem to point to this, inasmuch as whilst the constant current

is allowed to enter a house at 300 volts the pressure of the alternating is limited to 150. This seems to imply that the latter current is considered twice as dangerous to life as the former. If, however, it be remembered that the body is an electrolytic conductor, and that electrolytic conduction is invariably accompanied by decomposition, and further that, the living body not being homogeneous in its elements, and each different tissue thus forming a point of entry and of exit of the current with the accompanying electrolytic phenomena, it is obvious that a constant current of high voltage will on account of its electrolytic effects in the interior of the tissues be more dangerous to life, and its effects more difficult to recover from, than is the case with a current of an alternating character. Amongst the currents of commerce met with in this country are to be found constant currents having a pressure of 1000 volts.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

POISONING BY COCAINE; RECOVERY.

By E. J. WALKER, M.D.R.U.I., &c.

ON the afternoon of Jan. 11th I saw a healthy young man, under middle height and twenty-four years old, of whose illness the following is an account.

Being annoyed by toothache he had, about one o'clock that day, purchased from a druggist twelve powders, each supposed to contain fifteen grains of phenacetin. By a mistake of the dispenser he was given an equivalent quantity of hydrochlorate of cocaine—this I learned from the druggist, at whose request I undertook the treatment of the case. The patient, unaware of the error, divided one of the powders into two equal parts, and, putting one far back on his tongue, swallowed it in entirety. Having taken phenacetin on previous occasions he detected the difference, but when he wished to do so stated that he was unable to expectorate—at all events, he did not do so. I weighed the remainder of the fifteen-grain powder and as I found there were only six grains he must have swallowed between eight and nine grains of the drug. The effect, he said, was very rapid, a pleasant coolness spreading over his entire body, followed by a feeling of numbness in the mouth, tongue, and throat, changing very quickly to a sense of choking and desire to swallow, though he could not even perceive the presence of saliva. Returning to the druggist to inquire, he was given a stimulating draught; and still feeling queer, but in ignorance of what he had taken, he substituted a bowl of gruel for his ordinary meat dinner. Continuing to grow worse, he was sent home in a cab with the druggist, and on the way passed a large quantity of urine of a green colour. I saw him at his home at 5.30 p.m., and his condition was then as follows. He complained of a sense of constriction at the throat and over the heart; great difficulty in swallowing, but constant effort to do so; a dull, somewhat painful numbness (*sic*) in the stomach and abdomen; palpitation and an indefinite sense of oppression and mental dulness. I noted that the pupil light reflex was absent and that dilatation was present; the temperature was 97° F., and the reflexes were exaggerated; the pulse was almost uncountable. His appearance was that of a person partly under the influence of alcohol, but the most striking feature in the case was the state of the muscular system; he resembled a bad case of chorea, but the movements were much slower and more regular, the body was alternately rotated from side to side and bent at the same time, while the arms and legs were not still for a moment. A very strange effect was produced by uncontrollable action of the muscles of mastication. Owing to this he presented the appearance of a person chewing tobacco, and yet he was unable to eat a small piece of bread, and a cup of tea which he endeavoured to sip he spilled about the carpet. At times he showed some lividity round the lips and had difficulty in breathing. As the drug had evidently passed the stomach I did not attempt either to wash out that organ or to give an emetic; indeed, I fear that an attempt to do the former might have induced severe spasm. For the dyspnoea

¹ This improvised insulation supposes that indiarubber gloves and boots or mats are not at hand.

I used nitrite of amyl capsules with immediate benefit, and as the bowels had not acted I placed one minim of croton oil and five grains of calomel on the tongue. At 10 P.M. a great change was apparent. The purgatives had acted well, four or five liquid tarry motions had passed, the temperature had risen to 100°, the face was bright and clear, and the mind intelligent, the choreic movements had quite ceased and the masticatory almost, and the sense of oppression and dysprœa were gone. The next morning the man appeared to be quite well, but complained of slight weakness; two days after he was able to attend to his usual business.

Manchester.

AN ARTIFICIAL EAR.

By H. N. GROVE, L.D.S.

A MAN sixty-three years of age was admitted into the Queen's Hospital, Birmingham, in April, 1893, with an epithelioma of the left auricle. The greater part of the

auricle was removed by Mr. F. Marsh. A plaster-of-Paris cast was taken of the side of the head. An artificial ear was built up in wax to match the healthy one on the right side, and was then made in vulcanite and aluminium, tinted and

enamelled to harmonise with the complexion. No artificial contrivance (such as a spectacle frame) was made use of to support the artificial auricle, adhesion to the head being effected by means of a saturated solution of mastic in absolute alcohol.

Birmingham.

AN ATYPICAL ALBINO.

By A. J. BALMANNO ESQUIRE, M.B. LOND.,

SURGEON TO THE BRITISH HOSPITAL FOR DISEASES OF THE SKIN.

AN albino, although a rare, is nevertheless a familiar object, and, moreover, one of very undeviating type. Until the other day I thought that the type was absolutely without variation. I imagined that a person born with absolutely white hair and pigmentless skin (I am referring to those instances where the whole of the hair system and the whole of the skin are devoid of pigment) must necessarily have pink eyes and be unable to see clearly in bright sunlight, or, in other words, must needs be destitute of pigment in the iris and in the choroid; but, as it seems, it is not always so. A young man aged eighteen years, who has just come under my notice, is an albino. The whole of his hair system is white and the whole of his skin is pigmentless. He has presented this condition from his birth. However, the iris of each of his eyes is not pink, but, on the contrary, a very dark blue, and he can see as well in bright sunlight as he can at any other time. The glare of bright sunlight has never inconvenienced him in any way. In some instances of congenital complete albinism that I have met with more than one person in the same family has been affected. In one family a girl and two of her brothers were albinos. In this present case, however, there is but one albino in the family. He has four brothers and four sisters, one paternal uncle, three maternal aunts, and numerous cousins, but none of these relatives are albinos. His father has dark hair and his mother has flaxen hair. He presents a special condition, apparently in no way dependent on his albinism—which, however, is worthy of note, because I have met with it in at least one other albino,—and that is a constant oscillating movement of the eyeballs in the horizontal plane—that is to say, to and fro, from left to right and back again. The movement is so rotatable as to its range and so rapid as to its frequency that it is difficult to understand how he can acquire a clear idea of anything that he looks at; and he confesses that he does find it difficult to read print, but as to things in general he believes that he can see them as well as anybody else. I am not prepared to say whether this condition has or has not presented itself in every case of albinism that I have met with; for I had not taken account of the presence or absence of it (it not having arrested my attention) previously to the last two cases of albinism that I have seen—namely, this case and its immediate predecessor.

Weymouth-street, W.

ANKYLOSIS OF THE JAW OF LONG STANDING TREATED BY OPERATION.

By E. N. NASON, M.R.C.S. ENG.

THE patient, a man thirty-nine years of age, received a severe blow upon the right side of the face in 1882. It is not certain what the exact injury was, but it seems probable that the zygoma and condyle of the lower jaw on the right side were both a good deal damaged. No treatment was adopted, but after some little time the jaw could be moved freely without pain. It was not until two years and a half later that some restriction of movement began to be noticed. This slowly increased, and in two years' time the jaw became completely fixed, so that the teeth could not be separated at all. He remained in this condition for nearly seven years, living on liquids and sopped bread, as the power of mastication was completely lost. He came under my care in December, 1893, and was then more than half starved. After feeding him up for a week or so I operated upon the jaw on Jan. 7th, 1894. An incision was made along the posterior border of the ascending ramus of the lower jaw on the right side from half an inch below the zygoma to the angle of the jaw and carried down to the bone. Very considerable thickening, which seemed to be both bony and fibrous, was felt behind the

zygoma and around the neck of the jaw. The ascending ramus was then cleared with a raspatory three-quarters of an inch above the angle of the jaw and divided, and a wedge-shaped piece of bone with the base of the wedge (half an inch) posterior removed. This was effected with some difficulty partly by a keyhole saw and partly by cutting pliers as the bone was more than usually dense. There was no trouble with the inferior dental artery. The patient made an excellent recovery without constitutional disturbance and was able to masticate with very little pain on the third day. The mouth could be opened to the extent of seven-eighths of an inch, and very good lateral movement was obtained. The patient kept up passive movements very assiduously, and was given a graduated wooden wedge on which to measure the extent of the interval between the teeth. This has not tended to lessen during the last year, and the patient has at present perfect masticatory power, with free and painless movement, both vertically and laterally. This operation, the risk of which is small and the chief difficulty of which is the division of the bone without splintering or unnecessary damage, seems much more generally successful than excision of the condyle. The latter, as shown by Mr. Paul Swain some time back in THE LANCET,¹ has many risks, and often a result which is by no means satisfactory.

WESTMINSTER HOSPITAL.

ADDISON'S DISEASE OF VERY RAPID COURSE; REMARKS.

(Under the care of Dr. DONKIN.)

THIS disease is one which has attracted the special attention of pathologists and physicians since it was first described by Dr. Addison. The communication by Drs. Alezais and Arnaud (summarised by Dr. Allen J. Smith¹) is one of the most interesting recently published as a contribution to its pathology. They consider the process to be essentially one of tuberculous infiltration, the presence of tubercle bacilli having been repeatedly demonstrated in the affected supra-renal capsules. The process may begin in the cortex or in the medulla, and less often in the fibro-vascular zone about the capsule. Changes may be found in the neighbouring tissues as the result of such processes in the supra-renal capsules, as alterations in the abdominal sympathetic nerve, changes in the mesenteric glands, tuberculous disease of the spine and lungs, and alterations in the kidneys and urogenital organs. They regard as being near the truth the view that ascribes the phenomena of the disease—especially the prominent nervous symptoms, such as the sudden and complete asthenia, the vomiting, the lumbago, abdominal pains, and often the sudden death—to alterations in the abdominal sympathetics. They think, however, that the pathological facts thus far established are insufficient to base any theory upon, as in a number of instances the abdominal sympathetic has been found quite normal. Of forty-nine cases met with, the abdominal sympathetics were quite healthy in twelve instances. They believe, however, that the nervous symptoms arise directly within the capsules themselves, and have found undoubted nerve ganglia in the periphery of the organ as a constant element, and state that these bodies are always implicated in the capsular lesion of Addison's disease although heretofore overlooked. They cite three cases in support of their view. In one there was marked tuberculous change all about these ganglia, which were, however, intact, and no symptoms of Addison's disease were present; in the second the pericapsular ganglia, as well as the left semilunar ganglion and branches of the solar plexus, were involved, the symptoms of Addison's disease being present; in a third the pericapsular ganglia were

alone involved, the rest of the abdominal sympathetic system being intact, Addison's disease being manifest.

A man aged forty-seven years was admitted into Westminster Hospital on Nov. 12th, 1894, complaining of very frequent vomiting and great prostration, and died on Nov. 24th. He had been perfectly well, according to his own and his relatives' accounts, until five weeks before admission. He had had no previous serious illness, had not had syphilis, and was in all respects a temperate man. This illness began quite suddenly one day with pain in the epigastrium and vomiting about three minutes after a meal, since which time he had vomited after every meal and become steadily weaker. Three weeks before admission his legs began to feel numb, and he suffered from pains in the back and shoulders. On admission he was thin; his skin was generally of a dark, bronzed colour, most marked in the face, dorsum of hands, and axillae, least marked in the lower limbs. There were a few dark patches on the soft palate and on the inside of each cheek and of the lower lip. In answer to inquiry he said that his friends had told him about a week or so before his admission that he was getting darker in appearance. He was very feeble and walked with difficulty; but there was no discoverable alteration of sensibility over the trunk or limbs, and no muscular paralysis. The pulse was very small and compressible, and the first sound of the heart markedly indistinct. The breathing over the front of the right lung was harsh, but the thoracic signs were otherwise natural. Nothing abnormal was discovered on abdominal examination, nor in the urine, which was, however, of rather dark colour. After his admission the vomiting ceased, and the man seemed to improve. On Nov. 20th, his bowels being constipated, he had a dose of senna mixture. His bowels acted, but he started vomiting again. The temperature, hitherto normal or sub-normal, rose to 102° F. Next day the vomiting continued, and the temperature, after falling to normal, rose again to 104°, at which point it remained during the day following. The patient, however, then felt better, the vomiting having ceased. He talked cheerfully and said that but for weakness he felt quite well. On the night of the 23rd he slept well. On the 24th, at 6 A.M., he complained of cold feet, and shortly afterwards sat up in bed and "became quite-rigid, while his breath was very short." Recovering from this condition, he seemed to be fairly well until 8 A.M., when his breathing became short again, and he died in a few minutes. There was a cloud of albumen in the urine on the last day.

Necropsy on the afternoon of the day of death.—The body was fairly nourished, rigor mortis being present; the blood was fluid and dark-coloured, drying quickly. There was general bronzing of the surface, least marked over the lower extremities. The larynx was normal, and the thyroid gland small. There were a few old adhesions over the upper lobe of the right lung, but elsewhere the pleura was quite natural. In both lungs were several discrete, large, and pigmented fibroid tubercles, but there was no breaking down. In other respects the lungs were normal, as also were the mediastinal glands. The heart's muscle was firm and very dark; all its structures were apparently normal. The abdominal organs were natural, with the following exceptions. There were a few large pre-vertebral lymphatic glands, with no tubercles discoverable by the naked eye. The adrenals were very large, and quite converted into fibro-carcinomatous masses in which all traces of normal tissue were lost, though the general shape was fairly well preserved. (The semilunar ganglia were normal.) The kidneys weighed ten ounces. There was cortical atrophy of the upper half of the right kidney, the capsule around this portion being very thick and adherent to the subjacent areolar tissue. In other respects the kidneys were normal. The bladder was healthy, but in the centre of the prostate were numerous small and yellow caseous foci, clearly tuberculous. The prostate was not enlarged. The vesiculae seminales were normal. The epididymis on both sides, especially the left, was much enlarged from tuberculous deposit, and there were tubercles in the body of the right testicle.

Remarks by Dr. DONKIN.—The most important clinical points in this case are the very definite onset of the first symptoms and the extremely rapid course of the expressed disease. After searching inquiry it was established that the man felt and looked perfectly well until a little under seven weeks before he died. The pigmentation, as is most often the case in the more protracted instances of the disease, was not observed until after the important symptoms of vomiting and prostration had been established for some time. The

¹ THE LANCET, July 28th, 1894.

rise of temperature a few days before death must be noted as a symptom of infrequent occurrence. With this may perhaps be associated as a possible cause the advancing tuberculous affection of the prostate, epididymis, and testicle. The tubercles in the lungs were probably the earliest change of all those revealed at the necropsy.

CLAYTON HOSPITAL AND WAKEFIELD GENERAL DISPENSARY.

AN UNUSUAL CASE OF ADDISON'S DISEASE; SUDDEN DEATH; REMARKS.

(Under the care of Mr. PAUL STAR, senior house surgeon.)

TUBERCULOUS disease of the suprarenal bodies is an affection more common in men than in women, but the following case presents some other more important points of difference. From the usual type, which mark it as especially interesting. The most characteristic symptom of Addison's disease is the gradual development of debility without appreciable loss of flesh, and a sudden cardiac failure ending fatally without previous complaint of weakness is fortunately very rare. "It is probably not possible in any case to ascertain the exact date of the commencement of the disease; there are good reasons, indeed, for believing that the process of suprarenal degeneration is always far advanced before the clinical signs of the affection reveal themselves. Counting then from this latter date, the malady is sometimes remarkably rapid in its progress—proving fatal in the course of two or three weeks.—while sometimes it is prolonged for several years." Dr. Leva² has described a case the duration of which was supposed to have been eight years. This case exemplifies the advantages and advisability of holding a post-mortem examination in cases of sudden death.

A girl seventeen years of age was admitted to the Clayton Hospital on Jan. 27th, 1894. She had fallen in the street while on an errand, close to the hospital, and was brought to the institution on an ambulance. At the time of admission she was unconscious, motionless, and very pale; she was perspiring slightly about the face and neck, and the surface of the body was cold. There was no rigidity, and the sphincters were unrelaxed. The pupils were somewhat dilated, equal, and reacted to light. The conjunctival reflexes were present, but feeble. The tendon reflexes were normal, and there was no ankle-clonus. Respiration was shallow and the pulse was imperceptible. The cardiac impulse could just be felt and the sounds very indistinctly heard. The heart-beat was 65 to the minute. No injury to the head was apparent, and there was no distinct odour of the breath. Half a drachm of sulphuric ether was injected over the cardiac region, and a few minutes later the pulse could be distinctly felt at the wrist. The patient was put to bed and hot-water bottles applied to the legs and sides. She completely recovered consciousness in about half an hour. The pulse and respiration rapidly improved. She answered questions as to her name, previous health, &c., and said she felt quite well enough to go home. The heart and lungs were found to be quite healthy. The urine was normal. The patient was kept in bed and given some warm milk and about half an ounce of brandy. In about three hours the pulse again began to fall rapidly and became irregular in force and rhythm, the respiration at the same time becoming short and shallow. Sal volatile and brandy were exhibited, but there being no improvement in the pulse a drachm of ether was again injected over the heart. This had no effect, and the patient died a few minutes after the injection, the time between the commencement of the second attack and death being about ten minutes. The patient's mother said that her daughter had always been a healthy girl until about three months before the present attack, when she had to leave her situation owing to continued attacks of abdominal pain and vomiting. These symptoms were considered to be due to derangement of the digestive functions and had quite ceased about two months after their first onset, and she had again gone to work. Her family had always been healthy, and there was no history of any hereditary disease.

Necropsy.—A post-mortem examination was made fifteen

hours after death, when the body was found to be that of a well-nourished and finely developed girl. Rigor mortis was present in the lower limbs, but was passing off in the arms. There was no post-mortem staining, or pigmentation of skin, or mucous membrane, except below the umbilicus, where the skin of the abdomen was distinctly bronzed, forming a marked narrow line leading from the umbilicus to the pubes. The skin over the iliac regions was pigmented in a less marked degree. On opening the thorax the heart and lungs were found to be quite normal. The thymus gland was persistent and as large as that of a child twelve months old. It was normal in situation and weighed six drachms. The lobes were well marked. The abdominal viscera were normal. The stomach contained about half a pint of semi-digested food. The pelvic organs were normal. The adrenals were very large and tuberculated, hard to the touch, and on section showed no distinction between cortical and medullary substance. They cut like hard cheese and contained many cretaceous nodules, but no pus. Both the organs were surrounded by dense and tough connective tissue, and were bound down to the kidneys. The retro-peritoneal and mesenteric glands in their vicinity were enlarged and hard, but were normal in appearance on section. The semilunar ganglia and solar plexus were surrounded and compressed by fibrous tissue. The brain was normal. Microscopic examination of the adrenals showed the usual changes found in Addison's disease. Tuberculous growth was present in various stages; caseous centres were surrounded by small-celled infiltration with giant cells. A good deal of altered tissue was undergoing fibroid change. Sections of all other organs showed nothing abnormal. Unfortunately, the solar plexus and semilunar ganglia were not removed at the necropsy, so that a microscopic examination of their condition could not be made.

Remarks by Mr. PAUL STAR.—The chief points of interest about the case are—(1) the cessation of all symptoms for a month before death, the patient enjoying good health and following her occupation during that time; (2) the sudden death, this occurring about three hours from the time the patient fell in the street; (3) the presence of a large thymus; (4) the limited extent of the bronzing; and (5) there being no disease of other organs than the suprarenal capsules.

ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

A CASE OF CUT-THROAT INVOLVING THE LARYNX TREATED BY SUTURING; COMPLETE PRIMARY UNION; REMARKS.

(Under the care of Dr. ARNISON.)

THE ordinary rules of surgery as recently understood and expressed in our text-books left very little room for the exercising of the individual skill and discretion of the surgeon in charge of a case of cut-throat. If there was one thing about which there was unanimity it was the harm done by the insertion of sutures in such cases, and the great responsibility resting on the surgeon who ventured to use them. Dr. Arnison's treatment of his patient shows the excellent result which may be obtained by judicious suturing. The condition of these cases is often most unfavourable for the primary union of wounds: miserable, depressed, the subjects of chronic alcoholism, melancholia, renal disease, heart disease, or chronic phthisis—every injury, even the slightest, becomes of moment. Then, again the wounds vary very much in extent, depth, irregularity of surface and number of structures divided, and if there is any septic accumulation in a closed wound cellulitis of a spreading kind, only too frequently fatal, may ensue within a day or two. It is therefore necessary to exercise a careful selection before attempting primary union. For the notes of this case we are indebted to Dr. W. E. Harker, house surgeon.

A man aged forty years was admitted into the Royal Infirmary, Newcastle-on-Tyne, having cut his throat one hour previously. The skin incision began at the anterior edge of the left sterno-mastoid and tailed off a little beyond a corresponding point on the right side of his neck. Parts of the following muscles were cut: platysma, omo-hyoid (anterior belly), sterno-thyroid and thyro-hyoid, exposing on the left side the trunk of the vagus, which was lying internal to and on the same level as the vessels, which were uninjured. The thyroid cartilage was completely severed just below the pomum Adami, giving a good view of the interior of the larynx. The cut edges of the cartilage came accurately

¹ *Eristowe: The Theory and Practice of Medicine.*

² *Virchow's Archiv für Pathologische Anatomie und Physiologie und für Klinische Medizin, Berlin, Band cxxv., 1891.*

together, and were firmly retained in position by six catgut sutures. The divided muscles in turn were sutured over the cartilage. Deeply buried sutures were now inserted through the cellular tissue on either side of the larynx, so as to completely obliterate all spaces in which discharges might accumulate, after which the skin and subcutaneous tissue were united by silkworm gut sutures, entirely closing the wound, no drainage being employed. Careful asepsis was observed in dressing the wound. For three days after admission to hospital the patient was violently delirious (alcoholic), but was able to take liquid nourishment by the mouth from the first. At the end of seven days the wound was dressed for the first time, and the silkworm gut sutures were removed, primary union having taken place. Four days afterwards the patient was discharged.

Remarks by Dr. ARNISON.—The treatment in this case is quite opposed to the ordinary rules of surgery, but, given perfect asepsis, there is no reason why a wound in the throat should not heal as readily and completely as wounds in other parts. The difficulty in the case of wounds involving the air passage is that, however carefully the external wound may be treated, it becomes infected from the windpipe, with the resultant dangers of emphysema, cellulitis, &c. In this case I happened to enter the ward just as my house surgeon had finished suturing a somewhat jagged wound through the larynx, and I found he had closed it so carefully and effectually that I felt very confident that, with the same care in applying deep and superficial sutures to the external wound, and obliterating all dead spaces, it would heal throughout without drainage. My confidence was fortunately justified by the result.

MEDICAL SOCIETY OF LONDON.

A Successful Case of Paracentesis Pericardii. — The Treatment of Empyema in Children, based on an Analysis of Eighty-six Cases.

An ordinary meeting of this society was held on Jan. 23th, Sir WM. DALBY, President, being in the chair.

Dr. PERCY KIDD described a successful case of Paracentesis Pericardii, which is reported in full in another part of this issue.—Dr. SANSON in discussing the case, dwelt upon the presence of lead poisoning and of contracted granular kidney, and said that two years ago he had stated that he had never seen a satisfactory recovery from pericarditis under those circumstances. Since that time, however, he had come across two cases of the kind, both of which presented traces of old retinal hæmorrhages, a sign which added greatly to the gravity of the prognosis. The present case, he thought, was partly a true pericarditis and partly a hydrops pericardii judging from the quantity of fluid withdrawn. In some other forms of pericarditis such a mode of interference would hardly be justifiable, and in many there would be great difficulties in the way, as in what Dr. Sturges called pancarditis, an inflammation of the whole heart, with swelling of its substance, followed by pronounced pericardial adhesions, where the presence of fluid was only a small part of the problem.—Mr. MARMADUKE SHEILD fully agreed that paracentesis pericardii should be restricted to very special cases, and dissented from Dr. West's statement that it was an easy and satisfactory operation. There was great difficulty in diagnosing with certainty pericardial effusion, and especially in distinguishing between that and enlarged heart with adherent pericardium, while an injury to the heart wall or a rim on its surface might easily occur. It was an important point first to make a small incision in the skin and then to pass the trocar obliquely. Anæsthesia was generally necessary, especially in young children.—Dr. CARR recalled a case seen post mortem. During life there had been great extension of the pericardial dulness, and the advisability of tapping was discussed and decided in the negative. The pericardium was greatly enlarged in all directions, containing pus and lymph, the pus being packed away, as is often the case, at the back of the pericardium. The heart itself was anchored by firm adhesions to the front of the pericardial sac, so that practically if any attempt had been made at paracentesis the needle must necessarily have gone into the

ventricular wall wherever and however inserted.—Dr. EWART fully agreed with what Dr. Kidd had stated and with the conclusions he had quoted from Dr. West's paper. He had had several cases with very similar results. The most satisfactory was one in which twenty ounces of very bloody fluid were removed from the pericardium of a man aged about forty who was suffering from valvular disease with extreme dropsy and was in imminent peril. The relief was complete, though recovery was slow, the œdema lingering for a time; but the man was subsequently enabled to resume his occupation. The speaker had had the operation performed in cases of rheumatic pericarditis of severe degree, and with complications which made the safety of the patient depend on the immediate relief of intra-thoracic pressure. In one case, for instance, there was effusion into the three cavities of the chest, and all these were laid open, two of them at one sance, the patient recovering completely. He insisted strongly on the necessity of laying the pericardium freely open and cited cases illustrating the inefficiency of merely inserting a trocar.

Dr. CAUTLEY read a paper on the Treatment of Empyema in Children. Solis Cohen mentioned that absorption of pus from the pleural cavity was practically a myth, and said the late Dr. Sturges was of opinion that resection of rib was necessary and that the small mortality of empyema in children was due to improved treatment in this respect. Sutherland went even further and insisted on the necessity of washing out the cavity. Dr. Cautley had analysed a series of eighty-four cases with a mortality of 16·6 per cent. In respect of the cases in which no surgical treatment was adopted the fluid might of course be absorbed, but it might also rupture externally through the chest wall or internally through the lung. There was a considerable element of danger in leaving these cases to themselves, though in a certain proportion of such cases, either when left alone or treated by aspiration, absorption did take place. Of twelve cases treated by aspiration only one died, one ruptured externally, and one discharged through the lung. Of thirty-five treated by incision and drainage seven died, while of thirty-three treated by resection and drainage six died. A comparison of the two latter tables showed that the average age was practically the same, the mortality almost the same, and the duration of the after-treatment only differed in the matter of one or two weeks in favour of resection. It was a remarkable fact that five out of six cases under two years of age treated by resection died. An analysis of the fatal cases showed that in a large proportion death was not due to anything connected with the wound. The object of treatment was to remove the pus, to prevent reaccumulation, to procure complete re-expansion of the lung, and to leave behind no deformity. Although it was possible for small effusions to be absorbed, Dr. Cautley asserted most emphatically that in every case in which pus was present the only sound treatment was its evacuation. It might be conceded that aspiration was sometimes useful and might cure cases in which the pneumococcus was the primary cause. The disadvantage of aspiration was that thick effusions would not pass through the cannula, that it was impossible to remove all the contents of the cavity, thus leaving behind a focus of irritation, and, lastly, that pus rapidly reaccumulated afterwards. Moreover, there were certain dangers if the operation was performed too rapidly. On the other hand, it was useful in cases of urgency, in cases with thin sero-purulent fluid, and in cases of double empyema. The advantages claimed for resection were better drainage, facility for exploring the boundaries of the cavity, and for breaking down loose adhesions; also that there was less danger of hæmorrhage, that the chances of recovery were better, and that recovery was more rapid. Dr. Cautley pointed out that none of these advantages were proved by the experience of this series of cases, and that it was sometimes a distinct disadvantage to break down adhesions. The disadvantages of resection were that it was more severe, and, judging by the mortality, ought never to be employed in children under two years of age; and that there was greater liability to pyæmia and deformity of the chest. It ought, he thought, only to be had recourse to in cases in which the tube could not be inserted without and when drainage was imperfect, or for the cure of an old sinus. The tube should be short and only left in for a short time. Empyemata did not heal by granulation from the bottom, but by expansion of the lung, ascent of the diaphragm, and contraction of the chest wall. The tube should always be removed as soon as the discharge

became serous and scanty. If left in longer it became a source of irritation. Dr. Cautley stated that he had notes of a number of cases of double empyema, the treatment of which was practically the same, allowing a few days between the operations.—Mr. MORGAN said surgical proceedings would be attended very frequently by a more speedy and satisfactory result if brought to bear at an earlier date. Physicians had almost a superstition in favour of the aspirating trocar, and cases, he thought, were marred by the tentative measures its employment involved before a free opening was made. With regard to operation, Mr. Morgan greatly preferred resection to incision with drainage. Irrigation of the cavity, he thought, was a useful measure, as it detached a good deal of thick lining membrane.—Dr. MORISON concurred in the advisability of early evacuation of pus, and thought that aspiration was only of use in cases where, owing to some emergency, the more complete operation was temporarily impossible. He preferred chloroform as an anæsthetic and considered it safe, though serious results followed turning the patient on the side. The point of election was the sixth space, just in front of the posterior axillary line, and the method incision and drainage, most cases requiring the drainage-tube for little over a fortnight. He did not approve of irrigation, as he thought it was apt to set up irritation, which led later to restriction of chest movement. It was important during convalescence to adopt exercises for the expansion of the lung on the affected side. Resection, he thought, would prove to be only necessary in neglected cases.

CLINICAL SOCIETY OF LONDON.

Detachment of the Retina in Chronic Nephritis.—Chronic Self-inflicted Ulceration of the Throat.—Association of Respiratory Paralysis with Cardio-pulmonary Symptoms in Diphtheritic Paralysis.

AN ordinary meeting of this society was held on Jan. 25th, the President, Mr. J. W. HULKE, F.R.S., being in the chair.

Dr. SAMUEL WEST described two cases of Detachment of the Retina in the course of Granular Kidney. Case 1 was that of a woman aged twenty-two years who had suffered from headache, vomiting, and failure of sight for nine months, and who ten days before being seen in the hospital had become quite blind. She had had a severe attack of acute nephritis seven years previously, from which she had apparently never completely recovered. She presented the conditions of granular kidney and had marked albuminuric retinitis. Six days after admission she developed general purpura, which disappeared in a few days. Five days later detachment of the retina occurred (not hæmorrhagic). This rapidly extended till it involved the whole periphery except the upper segment. Three weeks after this a hæmorrhage occurred behind the orbit, which caused great pain but entirely resolved. She ultimately discharged herself from the hospital a month later in much the same general condition as on admission, but Dr. West did not think she could have lived long afterwards, though he was not able to ascertain what became of her. Case 2 was that of a man who said he had been in good health till two months before, when vomiting and headache attacked him. No history of previous illness could be obtained. It was only six days before admission that his eyesight began to fail, and in those few days he became blind. The case presented all the characteristic features of granular kidney, and albuminuric retinitis in a marked degree was present. Seventeen days later detachment of the left retina was discovered, but there were no symptoms to point to any great eye mischief. The patient rapidly lost strength, diarrhoea set in, which still more increased his asthenia, and he died a few days later. Attention was directed (1) to the existence of the disease, the occurrence of marked symptoms in granular kidney showing first that the disease had existed for some time, and that it was in an advanced stage, and secondly, that it had reached its termination; (2) to the suddenness of the onset of symptoms in granular kidney, which was most strikingly seen in failure of vision, so that a patient might become blind in but a few days after the first defects of vision had been noticed; (3) to the hæmorrhagic tendency, illustrated in one of these cases by purpura and retro-bulbar hæmorrhage; and (4) to the detachment of the retina, a very rare occurrence in granular kidney, these being the only cases observed by

Dr. West in a long series of cases, in all of which careful ophthalmoscopic examinations were repeatedly made.—Dr. COUPLAND, while concurring generally in the views expressed, asked what was Dr. West's experience as to the prognostic significance of albuminuric retinitis. Personally, he regarded it as a symptom of the gravest import. He, too, observed this symptom as the first one to draw attention to the granular condition of the kidneys, and his experience was that life was not much prolonged after the date of its discovery, rarely extending beyond twelve months. He pointed out that there were cases in which dimness of the vision was not complained of though the retinal changes might be well marked. He asked whether the prognosis was equally bad in these cases. He, also, had observed instances in which patients presented themselves with what appeared to be a sudden acute attack of nephritis, whose history, however, pointed clearly enough to the renal trouble being of long standing.—Dr. HALE WHITE recalled the case of a man who came to the hospital with albuminuric retinitis not associated with loss of vision. He improved considerably under treatment and left the hospital. Some time later, when he returned on account of some other symptom of Bright's disease, nothing abnormal could be detected in the eyes. This was the only instance he had met with in which the eye lesion had cleared up. Another case, that of a child aged seven years, was interesting in that the eye appearances were indistinguishable from those of albuminuric retinitis, although the child presented no other indication of Bright's disease. In reference to the occurrence of hæmorrhages he remembered one case in which a man came to him on account of a hæmatoma of the ear. It occurred to him to examine the urine and he found it contained albumen, and three months later uræmia developed. He commented on the rapidity with which interstitial nephritis ran its course in persons at or under thirty years of age. So much was this the case as almost to constitute a separate clinical variety of the disease. The occurrence of tubal complications supervening on chronic interstitial disease was, he said, a frequent termination in chronic cases.—Dr. WEST, in reply, agreed that the prognosis in cases presenting the appearances of albuminuric retinitis was extremely grave. So far as he had been able to follow up these patients life had rarely been prolonged more than a few months. It was almost the rule in these cases that vision was not affected for a long time after the onset of retinitis. He had seen several cases of neuro-retinitis in children which could not be distinguished by the appearances alone from albuminuric retinitis. He had hoped to have heard more in respect of hæmorrhages in different parts of the body; for example, he had never heard of hæmoptysis in this association. He had seen several cases of hæmorrhage from the bladder, and in a case that had come under his notice that day in the post-mortem room there had been profuse hæmorrhage from the bowels without any lesion to account for the bleeding.

Dr. FELIX SEMON described a novel form of Malinger—Chronic Self-inflicted Ulceration of the Throat. The case was that of an unmarried woman aged thirty-six, who complained of chronic ulcerated throat, which had existed, practically, without interruption, for four years. She had been treated by many previous advisers, but according to her statements had never been benefited. On examination the mucous membrane of the soft palate, the uvula, the arches of the palate, the tonsils, and the posterior wall of the pharynx were seen to be one mass of in part infiltration and in part ulceration; in other spots the mucous membrane was bright red, again in others it was denuded of epithellum, and still in others whitish shreds were seen, which in some patches were yellowish and even brownish in colour. The most remarkable thing was the abrupt termination of the affection above and below the region indicated. Neither in the naso-pharynx, nor in the œsophagus, nor in the larynx, could anything pathological be detected. On the occasion of her second visit, a fortnight later, having taken iodide of potassium in the meanwhile, the condition as a whole was pretty much the same, but the details had considerably altered, inasmuch as some of the ulcerations had healed and the membranous shreds had disappeared, whilst in others the affection seemed to have made progress. The fact, however, which had at once attracted the observer's attention—viz., that the affection abruptly terminated with almost parallel borders both above and below where the parts would cease to be accessible to the patient herself—was quite unchanged. Dr. Semon expressed to the patient's

mother his firm conviction that the whole affection was self-inflicted by means of nitrate of silver or nitric acid. The mother seemed not surprised, and, on the contrary, told him that years ago the patient had artificially blistered her breast and also at one time had blackened her face under the eyes in order to induce sympathy. She also stated that Mr. Hutchinson, who had been amongst the gentlemen consulted, had become convinced that the ulceration of the throat had been artificially produced. The patient herself denied having artificially produced the ulceration, but the denial was certainly not given with the surprise and indignation a person unjustly accused would show. She refused to go into a home for a week's time, where she would be under strict supervision, and the observer saw her no more. On inquiry, however, he learned from the mother that the throat remained much in the same condition, whilst the details of the affection varied from day to day, and that some time after the second consultation her throat and lips had suddenly become very white, the medical man consulted having assured her that it was not diphtheria, as feared, but had been caused by some application, probably nitrate of silver. The whiteness soon passed off. Dr. Semon had considered it right to put the case on record because, protean as the morbid power of invention of such patients is to discover new forms of suffering, he was not aware that the throat had even been chosen as the locality for self-inflicted injuries for that purpose.—Dr. GUTHRIE asked whether any anaesthesia of the pharynx was given in this case. It had occurred to him that anaesthesia of the parts might account for the patience and persistence with which the mutilations were carried on.—Dr. W. WHITE referred to the case of a young woman who amused herself with applying nitrate of silver to a small crack in the lip, with the result of giving rise to the most intense colouration of the skin from absorption of the metal he had ever seen.—Dr. WILBERFORCE SMITH urged that in the treatment of these cases it was most important to show no sympathy with the lesions complained of, but to concentrate one's inquiries on the measures suggested for their relief, such as cold baths, exercise, &c.—Dr. HALE WHITE related the case of a woman who presented some ulceration of the inter-arytenoid space which so little resembled any known condition that it was surmised to be traumatic. It transpired, on questioning, that she had been advised to take steam inhalations, and it was evident that she had taken them at such a temperature as to determine the lesion in question. It healed rapidly enough when these were discontinued.—Mr. FRANCE GOULD said that many years ago a girl was brought to him who was said to be suffering from two tumours of the jaw. He found a swelling on either cheek, over which the cheek was, so to speak, "puffed out." The tumours were said to have been slowly growing, and the girl apparently had great difficulty in swallowing, along with a horribly fetid discharge from the mouth. She resisted the introduction of the finger into the mouth; but he succeeded in extracting two masses of some tape-like material, which she had been accumulating in the cavity in order to attract notice and sympathy. He pointed out that some persons were peculiarly liable to discolouration of the skin and argyria, and he referred to a case recorded by Onodi, of Budapest, of a man who developed marked discolouration of the skin after a few applications of nitrate of silver to the nares.

Dr. PASTEUR read a paper on the association of Respiratory Paralysis with Cardio-pulmonary Symptoms in Diphtheritic Paralysis. The communication was based on an analysis of 32 cases treated at the North-Eastern Hospital for Children, Hackney. Of the 32 patients 26 were between two and six years of age. In 1 case there was no history of a previous attack of diphtheria; in 5 cases the history was somewhat vague; in the 26 remaining cases it was quite adequate. The cardio-pulmonary symptoms might supervene at any time between the first and the fifth or sixth week of the paralysis. Vomiting occurred in 13 cases, of which 9 were fatal. It was invariably associated with the onset of acute asphyxial symptoms (bulbar crises), and was of bad augury. The diaphragm became paralysed in 29 cases, of which 16 were fatal. In 4 cases which recovered there was associated paralysis of intercostal muscles and unusual physical signs were present stimulating lung disease. In 14 cases the onset of diaphragmatic paralysis was associated with increased amplitude of the respiratory movements of the lower ribs. Diaphragmatic paralysis was found to occur under two different forms—(1) insidiously as part of the peripheral paralysis; or (2)

acutely as part of a bulbar crisis. Of the 32 cases 19 died; in 17 of these there were bulbar crises. In 5 cases in which the diaphragm had been paralysed for two or more days there was an extreme degree of collapse of the lungs after death, especially of the right base, which in two cases sank entirely in water. In other cases in which the paralysis had been of very short duration, or non-existent, there was little or no pulmonary collapse. The extent and degree of collapse appeared to be directly proportionate to the duration and degree of the paralysis. In conclusion, the more salient points touched upon were summarised as follows: 1. The mortality in diphtheritic multiple paralysis is probably higher than current opinion would lead one to suppose. 2. Death takes place by asphyxia. 3. The fatal symptoms are, in the large majority of cases, of sudden onset, and suggest a bulbar origin. 4. Recovery from a bulbar crisis is exceptional. 5. Paralysis of the diaphragm is comparatively frequent, and may occur either acutely as part of the bulbar crisis, or may develop immediately as part of the peripheral paralysis. 6. The supervention of respiratory paralysis very seriously increases the gravity of the prognosis. 7. Whenever paralysis of the diaphragm, or other part of the chest wall, is long continued (two or more days) collapse of the adjacent lung is very liable to occur, and may give rise to definite physical signs. 8. The base of the right lung is more liable to be affected in this way than the left.—Dr. GUTHRIE said he was glad Dr. Pasteur had emphasised the fact that diphtheritic paralysis was not the mild, almost trivial, affection which it was formerly thought to be in this country. In France they had long been alive to the gravity of this complication. He hesitated to accept the assumption of the dependence of collapse of the lung on paralysis of the diaphragm or chest wall. Paralysis often occurred without collapse. He pointed out that the bronchioles were surrounded by a muscular layer as well marked as in the arterioles, and it was more likely that the collapse was due to paralysis of the dilator muscles. When one emptied an empyema, for example, the lung, theoretically, ought not to expand, but it did expand as the fluid was withdrawn, and this could hardly be otherwise than in virtue of the intrinsic muscular apparatus of the lung. He remarked that there were many pathological and clinical reasons for believing that diphtheritic paralysis was a central lesion—among others, the rapidity with which the symptoms came and went, and their occurrence in "crises." He asked if Dr. Pasteur had remarked the supervention of painful manifestations referred to the region of the epigastrium. Certain French writers had stated that this pain, associated with a rapid pulse, was of very unfavourable augury.—Dr. SIDNEY PHILLIPS declined to admit that diphtheritic paralysis was regarded as so trivial a matter in this country as the previous speaker appeared to think. The proportion of 39 cases of paralysis of the diaphragm out of 64 cases of diphtheritic paralysis was curiously large, and the proportion of recoveries after paralysis of the diaphragm was hardly less remarkable. He himself had never seen a patient with well-marked paralysis of the diaphragm recover. Diphtheritic paralysis might occur later than six weeks after the attack, and he knew of one case in which it came on nine weeks after, the patient dying suddenly. In another case a child was discharged from one hospital as cured of diphtheria, and four weeks later was admitted to the Paddington Hospital for Children presenting symptoms of complete general paralysis, from which it died. This made it probable that the death-rate from diphtheritic paralysis was in reality greater than was usually believed. This fact tended to vitiate the statistics of the antitoxin treatment, sufficient time not having been allowed to elapse to be certain that the recoveries were established. It occurred to him that many of these supposed instances of lung collapse were not really collapse at all. Trousseau long since pointed out that when there was spasm of the bronchi or bronchioles one could obtain the most wonderful physical signs by auscultation. He mentioned that he had seen one case of unilateral paralysis of the chest wall.—Dr. PASTEUR, in reply, said he did not suggest that paralysis of the chest wall or diaphragm was the only factor in the production of the collapse of the lung, but only as being one important factor. Many of his cases of collapse were verified as such in the post-mortem room, and he had been most careful to exclude cases as to which there was the slightest doubt. The paralyzes sometimes occurred in crises suggesting a central lesion, while in others the distribution was suggestive of a peripheral lesion. Far from having noticed epigastric pain in these cases, he had always been struck by the curious absence of

painful manifestations. He had not included in his notes any cases of early death from cardiac failure, because these occurred at the end of the primary disease, while he had only taken cognisance of cases in which the paralytic symptoms supervened three weeks or so after.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

Epidemic Diseases in the Royal Navy.

A MEETING of this society was held on Jan. 18th, Mr. SHIRLEY MURPHY, President, being in the chair.

Fleet-Surgeon THEODORE PRESTON read a paper on *Epidemic Diseases in the Royal Navy*. It was impossible, he said, to study their history without regard to the great improvement in the diet and consequent increase of resisting power that had taken place during the last hundred years, beginning with the introduction of lime-juice and other reforms in 1795 the substitution of iron tanks for wooden water-casks, and more recently of distilled water fresh daily. Not less important was the general use of tea, coffee, or cocoa in place of rum. Before 1825 half a pint of raw spirits had been served out to everyone, it was then reduced to four ounces, and at present even that was issued freely diluted to those men only over twenty years of age who applied for it personally, and no sale or barter was allowed. Prior to 1795 the service was continually exhausted by scurvy, sloughing ulcer, typhus fever, and dysentery; it was impossible to keep a fleet at sea for many weeks together, and the mortality on long voyages was awful, as when Admiral Hozier, sailing to the West Indies with seven ships of the line, lost the whole of his crews twice over, and Lord Anson a few years later four-fifths of his from scurvy alone. Yet its nature and the virtues of lime juice had been known since early in the seventeenth century, and the experimental use of two-thirds of an ounce of lemon-juice daily on H.M.S. *Suffolk* had shown that a crew could be kept at sea for 162 days without a single case of scurvy. The result of the earliest reforms was seen in the rapid disappearance of scurvy and sloughing ulcer, and the fall of the death rate from all causes from 123 per 1000 in 1779 to 14 in 1813. Scurvy had, however, reappeared on several occasions, as in 1838, when there were twenty cases of so-called "night blindness" on board H.M.S. *Winchester* on her voyage to and from the Cape, and in the following year fifty-five cases of severe scurvy among the crew of H.M.S. *Alligator* during their laborious and unsuccessful efforts to establish a settlement at Port Essington in North Australia. Next, in 1854, the crews of the Baltic fleet suffered badly and two men died. The only cases since that time had been those of a few Kroomen in 1870-71 and the sledging parties of the Arctic Expedition in 1878, among whom 59 cases occurred with 4 deaths, though not being provided with fresh meat or lime juice. Passing by two alleged cases of plague, which were probably anthrax, the first authentic record of that disease in the navy was that of an outbreak in 1841 among the men landed at Kaiffa from the wreck of H.M.S. *Zebra* and the crew of the *Castor* sent to their assistance; of thirteen cases nine died, but the disease, which appeared to have been contracted in Acra, did not extend on board the *Castor*. Yellow fever had been familiar to navy surgeons for over 200 years, but he would begin with the remarkable outbreak at Ascension in 1839. It appeared at Sierra Leone after an absence of seven years, on board some merchant vessels, and spread to H.M.S. *Curlen*, which lost half her crew and two surgeons. She sailed thence to the Gambia, landed her sick, and set up an epidemic among the whites, the first and last known in the colony. Later in the year three ships, having contracted yellow fever at Sierra Leone, proceeded to Ascension, where they landed their sick with a semblance of isolation, but officers' effects and clothing were publicly sold. The fever, which had already attacked nearly the entire crew, broke out in the garrison, persisting for three months, when it ceased, and the inhabitants would never allow it again to approach their shores. He then described a succession of epidemics in the West Indies between 1863 and 1869, in 1873, and in 1882, which illustrated its intense infectiousness but varying mortality. At first hygienic precautions seemed useless; but later, and especially since the practical abolition of the bilge, its preventable character had been shown, and the number of cases and of deaths respectively in the navy had fallen in successive quinquennia from 1863 to 1892 as follows: 267 and 142, 178 and 77, 106 and

49, 54 and 21, 47 and 14, and 15 and 9. Much of the "dysentery" of past days might have been cholera; but the first clear account was that of an outbreak at Malta in 1837, when the disease, which, though prevalent in Italy and Sicily, had been kept out of the island by a rigid quarantine, was introduced aërially into a large poorhouse from the exposure of linen on board a Turkish man-of-war and other vessels moored in close proximity in the quarantine harbour. The inmates, 600 in number, were removed to barracks near the Grand Harbour, but no fewer than 400 out of the 600 died, while the garrison and civil population suffered heavily. Several ships of war calling at the island for a day or two and taking in water from the naval tanks were infected, and the navy had, in all, 219 cases with 38 deaths on that station. After describing the introduction of cholera into the allied armies and fleets in the Crimea and Baltic, and in particular the aerial infection of H.M.S. *Britannia* from the French troopship and the cholera camp on shore—facts familiar to all epidemiologists—he passed on to the outbreak on the China station in 1862, remarking that in the expedition against Khadung the naval brigade had 141 cases with 80 deaths, while the troops accompanying them, but bringing their own water from Shanghai, escaped entirely. In 1865 Malta was invaded from Egypt, the only precautions taken being an absurdly antiquated quarantine; the native population suffered heavily, 63 per cent. of those attacked dying, but only three cases occurred in the naval forces, all having been contracted on shore and ending fatally. Single ships had from time to time been infected by intercourse with the shore in different parts of the world where the disease was prevalent. After repeating the classic story of Admiral Kempenfelt's fleet in 1782, and with considerable detail the history of the influenza epidemic of 1837 on the home and Mediterranean stations, he observed, with regret, that no statistics were available for the period between 1843 and 1854, when they were resumed with the Russian war. In that epidemic there were 5018 cases and 3 deaths in a strength of 14 000 in the Black Sea and Baltic fleets. Many limited outbreaks had occurred on board vessels in different climates, but that on H.M.S. *Surly* in 1863, while cruising on the coasts of California and Mexico, was of special interest. When in the Gulf of Tehuantepec, 140 miles off the shore, a strong breeze set in from the land and lasted a considerable time, bringing with it a heavy perfume of flowers. Three days later cases of influenza began to appear in rapid succession, and on their arrival at La Union in San Salvador they found an epidemic of influenza raging, and recognised in the forests the perfume of the flowers. In 1750 one-fifth of the men enlisted died annually from small-pox, and in 1800 it broke out twenty times in the Channel fleet and compelled the return to port of one ship after another. In 1808 vaccination was officially "recommended," advice which was repeated in 1814 and 1825; but the first compulsory order was in 1864 requiring all new entries to be vaccinated, followed in 1871 by one for revaccination and another in 1873 enforcing the vaccination of "foreigners"—i.e., of Kroomen, Lascars, &c.—with the result that there had been a steady fall from between 5 and 8 cases and 0.3 to 0.6 deaths per mille in the sixties to 0.09 to 0.36 cases and 0.0 to 0.06 deaths during the last twelve years. Most of the local outbreaks occurred on the China station, where there had been great difficulty in obtaining lymph, which the establishment by the Japanese Government of farms for the supply of calf lymph had since removed.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

The Connexion between Female Labour in Factories and the High Infant Mortality in certain Manufacturing Towns.

A MEETING of this society was held on Jan. 21st, Mr. S. R. LOVETT, President, being in the chair.

A discussion on this subject was opened by Dr. PORTER, medical officer of health, Stockport, who endeavoured to show that the excessive mortality was to be ascribed rather to the insanitary conditions amid which the children were reared than to the mere fact of the employment of the mothers, though he admitted that it necessitated artificial feeding with its train of ills—diarrhoea, rickets, &c.—and that premature births were more frequent among women

engaged in textile industries than in rural populations; but the influence of the grossly insanitary conditions of most of our manufacturing towns, especially as to the housing of the working classes and the disposal of excrement by the midden system, was a disgrace to the country; huge leaky pits often abutted on the walls of the houses, in which the liquid and solid excrement of a whole court, it might be, putrefied, and exhaled a sickening stench. It was no wonder that the medical officer of health of Crewe found the infant death-rate four times higher in the quarters where middens were in use, and he had found nearly the same at Stockport, where the infant death rate among the legitimate was 225 and among the illegitimate 594 per 1000. Indeed, the life assurance companies would not take illegitimate children under three years of age; but he did not believe that the practice of insuring the lives of children led to neglect. The payment of £2 was not worth the risk of courting inquiry, and agents of life assurance associations had assured him that the insurers belonged to the most respectable and steady of the working classes, and that the mortality was lower amongst these children than among others. In fact, the Bill directed against was withdrawn on the ground of insufficient evidence. If children were the victims of foul play it was rather by the reckless use of soothing syrups &c., under which name, or that of syrup of violets, Dr. Jones, in his Howard Essay, stated that 39 lb. of laudanum were sold every week in one town, and in another two druggists paid £5 each and costs rather than face the exposure of a trial. The law at present forbade the employment of women within four weeks after confinement, and a deputation to the Home Secretary had recommended an extension of the period to three months; but Mr. Asquith had shown from the Registrar-General's returns a greater increase in some manufacturing towns, as Wolverhampton, where women were not employed, and Dr. Reid's statistics did not take into account the simultaneous increase in the general death-rate in the same towns. Such prohibition of female labour was impracticable; some drunkards did live on the wife's earnings, but more often they kept together the home of the unwilling idler, and no law could prevent "charing." Again, the infant mortality was greater in the first month than in the second and third together, due partly to work during the later months of pregnancy, and a month's rest before delivery would be of great advantage. Inquiries among mill owners and overseers led him to the conviction that more stringent legislation would be impracticable, since the expected date rested on the woman's statement, and, though often warned, their confinement generally occurred within a few hours of leaving work, sometimes indeed in the mill. Even the four weeks rule was evaded, for if the overseer refused to readmit a woman she would get work where she was not known; and she frequently lost her post, as it was, unless she could find an equally efficient substitute. Crèches, or public day nurseries, had been recommended and tried, both at the mills and elsewhere, but without success, for the mothers preferred a neighbour whom they knew living near their own homes. Indian women, however, nursed their children in the mill. The only remedy he saw was the extension of the Infant Life Protection Act to all caretakers excepting near relatives, with annual licences and inspection, and notice to the coroner of all deaths, although it would provoke resistance at first.

Dr. REID defended his position. In his county of Stafford there were many towns with from 10,000 to 30,000 inhabitants, some wholly devoted to iron founding and others to pottery. The sanitary conditions were practically identical, but in the former no women and in the latter many were employed. In these the increase of the infant mortality in ten years had been 23 per cent., as against 18 per cent. for manufacturing towns generally. Mr. Asquith's figures were fallacious, for in the case of Wolverhampton, instead of comparing the decades 1871-80 and 1881-90, he had taken the years 1885 and 1893 which happened to give the lowest and the highest infant death-rates on record. True, the infant mortality had risen in the last ten years; but then two industries had sprung up, galvanising and japanning, the one largely and the other wholly conducted by women; while prior to 1880 the sole industry of the town was the iron-works, employing only men. He maintained that the increase in the general death-rate alleged by Dr. Porter was wholly due to the rise in the mortality among infants. He still advocated the three months' absence from work, which would carry the infant through the most critical period; whereas

one month was of no advantage to the child, since it was not worth the mother's while to nurse an infant for so short a time, and the husband's wages were, as a rule, sufficient, though the additional twelve or fifteen shillings earned by the wife were a temptation.

Dr. TURNER could not agree with Dr. Porter, for the infant mortality from diarrhoea was not confined to the more insanitary towns. It was wholly a question of artificial *versus* "aseptic" breast feeding. The infant death rate was formerly the same at Leicester as at Portsmouth, but on the introduction of the shce trade, owing to disputes at Northampton, it rose in one year 50 per cent., and a further rise followed the transfer in 1860 of the silk ribbon industry from Coventry, where it was superseded by the cycle and sewing machine manufacture. There the release of the women led to a corresponding fall in the infant deaths, except in 1870, when the Franco-German war caused a transitory revival of the silk industry. Infant diarrhoea was almost unknown in Old London, insanitary as it was, just because feeding bottles had not been invented. At Much Hadham, a large village where the children were invariably breast-fed, the opening up of an ill-constructed system of communicating cess-pits and sewers was followed by an outbreak of diarrhoea which spared the infants even when their mothers were attacked.

Dr. SPOTTISWOODE CAMERON, Dr. REGINALD DUDFIELD, and others having spoken, Dr. PORTER replied. He did not deny the importance of female labour as a cause, but maintained that it was one of many, and he deprecated exaggeration and the advocacy of measures which, however desirable in themselves, would be found impracticable.

ÆSCULAPIAN SOCIETY OF LONDON.

Exhibition of Cases.—Strangulated Hernia.—Diphtheria.

A MEETING of this society was held on Friday, Jan. 25th. Dr. A. T. DAVIES exhibited a young woman the subject of extensive superficial Lupus of the Face and Neck who had been under treatment for seven months with thyroid extract. Steady and marked improvement resulted, the patches fading and becoming more flattened. There was no history of syphilis or tubercle. Dr. Davies regarded the effect of the thyroid treatment as suggesting a possible relationship between myxœdema and tubercle.—Mr. F. C. WALLIS mentioned two cases of severe lupus invading the nose and adjacent parts in which great benefit resulted from a combination of skin grafting with the thyroid treatment. He also showed a broad and sharp edged knife devised by him for shaving off large portions of skin for grafts.—Mr. STEPHEN PAGET showed a case of Acromegaly. Reference was made to a similar case observed in the dissecting-rooms at Edinburgh University seventeen years ago, in which the pituitary body was then noticed to be much enlarged.

Mr. PAGET read a paper giving details of twelve cases of Strangulated Hernia in which the bowel was found on operation to be gangrenous. Only one of the twelve recovered. Almost every case was practically hopeless when admitted to hospital. The reluctance of patients to undergo operation, the want of due assistance by practitioners, the deceptive character of such attacks, and partially successful reduction had each their share of responsibility for the fatal delay in operating. As regards the operation, resection was in several cases impossible on account of the extent and position (the large intestine) of the gangrene. Extreme gentleness and care in examination of the hernial mass might have done something—possibly not much—to alter the result, but the whole series of cases formed a protest against the danger of delay.

Dr. B. G. MORISON read notes of three well-marked cases of Diphtheria, two of them severe and relapsing, treated successfully with antitoxin diphtheria. The false membrane cleared rapidly and no sequelæ had been observed. In one case laryngeal symptoms were present and disappeared after the injection.

MIDLAND MEDICAL SOCIETY.

Exhibition of Cases.—Post partum Hæmorrhage.

THE fifth ordinary meeting of this society was held on Wednesday, Jan. 6th, Mr. T. F. CHAVASSE, President, being in the chair.

Dr. LESLIE PHILLIPS showed a curious case of Pityriasis

Rosa.—Dr. PURSLOW showed a Fœtus from a case in which Decapitation had been necessary to complete delivery.

Dr. MALINS opened a discussion on the treatment of Post-partum Hæmorrhage. He alluded to the importance of the subject to the majority of the society who were engaged in the practice of midwifery, and pointed out the value of trustworthy and accurate knowledge in times of emergency. The natural manner in which hæmorrhage was arrested after delivery was pointed out. Considerable stress was laid upon the prophylactic treatment and the treatment of those called "flooders." The order in which the treatment was enjoined after delivery of the placenta was: (1) manual stimulation, external and internal—bimanual compression also of the uterus in a position of antelexion was noticed; (2) the application of cold and heat; (3) the use of ergot by mouth and hypodermically; (4) the application of astringents, such as iron, by injection, swabbing and tampon, and the use of vinegar; (5) Dührssen's method of plugging the uterus; and (6) transfusion. The details of the above methods were considered, and the relative importance and advantage of each pointed out from the speaker's experience.—Mr. ALFRED FREER said that the hæmorrhage in some cases began before delivery was complete. The most dangerous cases were those in which the hæmorrhage took place between the birth of the child and the expulsion of the fœtus, and in such cases separation and removal of the placenta were of the utmost importance. Women who indulged in beer excessively were often "flooders," and a purgative course of treatment before labour seemed an admirable prophylactic. Vinegar and water had in his hands been of great service in some cases, and he preferred it to iron, which if used should be in very dilute solution. Neutral iron alum was to be preferred to the perchloride.—Mr. A. H. EVANS said that post-partum hæmorrhage was very rare in well-conducted labours. The worst cases were those in which, in the absence of a medical man, there had been only an imperfect delivery of the placenta. The passage of the hand into the uterus and a thorough cleaning away of all coagula were very important items in the treatment. He called attention to distension of the urinary bladder as an occasional cause of difficulty in contraction of the uterus, and alluded to the importance of a quick pulse after delivery as a warning of impending hæmorrhage.—Dr. PURSLOW found that the most troublesome cases of post-partum hæmorrhage occurred in primiparae after the application of forceps under chloroform for protracted labour. He insisted upon the importance of never losing the manual control of the uterus after delivery, and always gave a dose of ergot after delivery.—Mr. DONOVAN said that the treatment of post-partum hæmorrhage really began before delivery. The child should always be made to advance by forceps if the uterus when contracting forcibly was not capable of advancing it. Exhaustion and uterine inertia were thus avoided. When the head was delivered the advance of the body might be retarded and the uterus thus given time to contract. Ergot should be given as a routine treatment after the birth of the child.—Dr. E. UNDERHILL laid stress on the importance of anticipating if possible the occurrence of hæmorrhage by a careful inquiry into the history of previous confinements. The uterus should be grasped with the hand immediately the child is born. He urged the importance of supporting the strength of the patient and the administration of easily assimilated food in cases of weakness.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Spina Bifida.—Ovarian Tumours.—Glandular Proliferous Cyst of Right Ovary.—Uteri removed by Vaginal Hysterectomy.—Clinical Report of the Rotunda Lying-in Hospital.

A MEETING of this section was held on Dec. 21st, 1894, Dr. PUREFOY, President, being in the chair.

Dr. W. J. THOMPSON exhibited a patient with a Spina Bifida who had the following history. The patient was three months old and had a spina bifida at birth as large as an orange, flaccid, translucent, and covered with a thin bluish membrane. There was complete paralysis of the lower extremities, but not of the rectum or bladder. The laminae were wanting, and the bony ring around could be distinctly traced. The legs were everted from the hip-joint, and the left foot was a well-marked specimen of talipes calcaneus.

The case was either a meningo-myelocele or a syringo-myelocele—probably the former. For about one month there was no change in condition, and at the end of that time the tumour got smaller and more tense, and the skin healthier; the legs also regained power, and eversion became less marked. Two weeks after the improvement in the legs was noted hydrocephalus commenced and had gradually increased, the circumference of the head measuring now twenty inches. The bones were widely separated, the fontanelles greatly enlarged, and the sutures could be easily traced. There was distinct fluctuation, and the veins were enormously enlarged. From the statistics of the Clinical Society of London it would appear that spina bifida occurs once in 1000 births, and it was associated with hydrocephalus once in 10,000 births. The family history was good, but the first child had an enormous nævus. The treatment had consisted of firm pressure with simple antiseptic dressing. Dr. Alfred Smith thought that it could only live a week or two.—Mr. Croly, Dr. Macan, and Dr. Purefoy made observations on the case. Dr. Thompson replied.

Dr. ALFRED SMITH showed two specimens of Ovarian Tumour—(1) a large Papillomatous Cyst, removed from a patient aged fifty-two, recovery good; and (2) a small Ovarian Tumour removed from a patient aged thirty-two. The patient had been ailing for the past twelve months, and complained of great pelvic pain and of severe pain down the right leg, which caused the patient to walk very lamely. There were many attacks of hysterical convulsions, the seizures occurring chiefly when the patient was alone. On examination under ether a tumour the size of the fetal head was found jammed in the pelvis; it could not be released, being hitched under the promontory of the sacrum. After an easy operation recovery was uneventful, and the patient walked without showing any evidence of lameness. There had not been any recurrence of the convulsions. The operation was performed on Nov. 28th. Dr. Macan, Dr. Smyly, and Dr. Purefoy made remarks on the case, and Dr. Smith replied.

Dr. J. H. GLENN exhibited a Glandular Proliferous Cyst of the Right Ovary.

Dr. F. W. KIDD exhibited two Uteri removed by Vaginal Hysterectomy and gave an account of the operations.

The following Clinical Report by W. J. SMYLY, M.D., Master; J. H. GLENN, M.B., and H. TWEEDY, L.R.C.S.I., Assistants, of the Rotunda Lying-in Hospital for the year 1892-93 was submitted to the meeting:—During the year ending Nov. 1st, 1893, 1238 patients were confined in the hospital and 2105 at their own homes; total, 3393 cases relieved. In my former report of the Lying-in Hospital I stated that the morbidity of the patients delivered in the wards was a safer test of the precautions taken to guard them from septic infection than the actual mortality, and the present report confirms that opinion. By morbidity I meant the number of cases in which the temperature even once exceeds 101.4° F. The details of the fatal cases are even more convincing, three out of the five having been admitted in an advanced stage of the disease; a fourth was infected from an abscess in the pubic symphysis, the genital canal remaining healthy; and the fifth was the result of a surgical operation (sympphysiotomy). Forty-one women aborted, eighteen of whom required no assistance. In three the uterus was emptied by the finger alone, and in nineteen the uterus was curetted after the removal of the ovum. One patient only was plugged. There were three cases of transverse or oblique presentation. All the mothers did well. There were eight cases of placenta prævia with one death, the result of pulmonary embolism. In three cases the children were born dead. Two cases were left to the natural forces of labour. Forceps were applied in one instance, and in the remaining five cases turning and bringing down a leg through the cervix, then leaving the woman to be delivered by the natural process. As regarded accidental hæmorrhage, there were twelve cases with two maternal and six fetal deaths. In three cases no special treatment was required; in three version alone was adopted, while the remaining six cases were plugged and bound with a tight binder. Version was performed subsequently in three of these cases as further treatment. The vaginal plug, when efficiently applied before the rupture of the membrane, stopped the hæmorrhage in every instance, and had the further advantage of inducing labour pains and causing the rapid dilatation of the os. There were twenty-four cases of post-partum hæmorrhage. Six were traumatic (due to lacerations of the cervix), in three the rents were closed by suture, and in three plugged with

Iodoform gauze. The others were atonic—viz., in six the placenta or membranes had to be removed manually; two were plugged with iodoform gauze; and all were douched with hot water. The perchloride of iron was not used in any case. One patient with a submucous myoma died. There were ten cases of contracted pelvis; eight were flattened pelvis and two generally contracted flattened pelvis. The measurements were taken with Skutsch's pelviometer or Dr. Bullit's modification of the same. Four of these were delivered by forceps, one by perforation, two by induction of premature labour, and three by symphysiotomy. Version was performed eleven times (November, 1892, to November, 1893). In two instances external version was accomplished. In one of them a transverse presentation was changed into a vertex. In the other a head was converted into a breech as part of the treatment in ante-partum hæmorrhage. Symphysiotomy was performed three times, and, though one patient died, I hold it to be a good method of delivery in suitable cases. There were nine cases of eclampsia during the year. The mortality was in mothers two, in infants five. The urine in every case was found highly albuminous.—Dr. MACAN congratulated Dr. Smyly on the result of the report. There were very few cases of septicæmia, and most of them were brought from the outside. He considered that symphysiotomy was a very difficult operation, requiring three assistants and very skilled after-treatment. He thought that the consensus of opinion at the meeting at Rome was that it was unsuited for ordinary practice.—Dr. ATTHILL said that the question of plugging or not for accidental hæmorrhage was a very old one. It used to be laid down that it was absolutely wrong to plug in accidental hæmorrhage, but he had discovered that many cases of supposed placenta prævia which were plugged did very well, but turned out not to be cases of placenta prævia.—Dr. ALFRED SMITH entirely agreed with Dr. Smyly in thinking that morbidity is the real test of antiseptics employed. The removal of adherent placenta was considered one of the most dangerous operations in midwifery, but in the report he found that nineteen had been removed and that there was no record of death.—Dr. GLENN compared the statistics of morbidity within the last four years, and showed how greatly it had fallen off—first year, 185; second year, 117; third year, 94; fourth year, 60.—Dr. PARSONS said that the more he thought of the treatment of eclampsia by chloroform the less he liked it. That the convulsions could be stopped by it was perfectly certain, but he did not know whether it was a good thing to stop the convulsions.—Dr. CROLY thought that in convulsions nothing was so good as cold effusions to the head continued for a considerable time. They had the advantage of not depressing the patient.—Dr. PUREFOX looked rather unfavourably upon plugging in accidental hæmorrhage. He had seen no bad results follow the use of perchloride of iron.—Dr. SMYLY, replying, said that unfortunately a death had occurred from post-partum hæmorrhage, which commenced two or three hours after delivery in consequence of a submucous myoma. The uterus was left well contracted, but violent hæmorrhage came on again. He now came to the chief point in the report—namely, the treatment of deformed pelvis. Symphysiotomy was only a very small part of the treatment. If the head did not mould the forceps must be tried, or failing them, there was the choice between symphysiotomy and perforation. He shrunk from perforation on moral grounds. He admitted Dr. Macan's objection to symphysiotomy. The number of assistants required prevented its being used in general practice.

ERRATUM.—In our report last week of the meeting of the Leeds and West Riding Medico-Chirurgical Society, the remarks made by Mr. Cant should have ended with the sentence "and referred to Mr. Greig Smith's recent paper on the weakness of some of these adhesions." The remarks after this were made by Mr. Ward.

THE SUNDAY LECTURE SOCIETY.—The third series of lectures given by this society, of which Professor Huxley is the president, will begin on Sunday afternoon next, at 4 P.M., in St. George's Hall, Langham-place. The first lecture will be given by Mr. A. S. Woodward, the subject being the Restoration of Extinct Animals.

Reviews and Notices of Books.

A Treatise on Hygiene and Public Health. Edited by THOMAS STEVENSON, M.D., F.R.C.P., and SHIRLEY F. MURPHY, M.R.C.S. Vol. III.: Sanitary Law. London: J. & A. Churchill. 1894.

THE student of the first two volumes of this valuable work will, we think, after reading the third volume, agree that it forms a fitting completion to the treatise; and it will, too, be readily conceded that the anonymity of the articles is a fact of small importance when compared with their intrinsic excellence and the assurance of the editors that the writer in each case "is officially engaged in the administration of the law of that part of the United Kingdom to which his article relates." Volume III. does not lend itself to review in the same manner as did the two preceding volumes, and when we have said that the book is an able disentanglement and collation of the law as it relates to the several matters concerning, or likely to concern, the medical officer of health, we have in large part given the book its due.

The law appertaining to public health in England and Wales, in London, in Ireland, and in Scotland, is treated of separately in this volume, and in each case the most recent legislation is embraced. The reader will find, for instance, that in England the sanitary areas are spoken of in the terms of the Local Government Act, 1894. In a brief introductory review of the Public Health Acts in England and Wales the author of that part of the volume refers to the manner in which their value would be greatly enhanced were they so consolidated and amended as to be readily understood by the general public in whose interest they were framed, and he also draws attention to the difficulty which a lay reader must necessarily find in mastering the details of the several Acts, many of which are modified and partly repealed by later enactments.

No one who has endeavoured to unravel the intricacies of the laws relating to public health in England and Wales would be likely to do otherwise than heartily endorse these sentiments. The general arrangement of the book is such as cannot fail to commend itself to medical officers of health and students of sanitary law, as, the matter being dealt with under subject headings, it is possible to obtain by a minimum amount of reading a comprehensive knowledge of the law in regard to any subject upon which information is desired. In making this statement, however, we do not wish to imply that a thorough knowledge of the law can be obtained except by a study of the Public Health Acts themselves, but rather that a grasp of their main provisions sufficient for the medical officer of health in the performance of his daily duties will be procured.

The sanitary provisions of the Local Government Acts, 1888 and 1894, are well set forth, and considerable space is devoted to such subjects as the Burial Acts, the Housing of the Working Classes Acts, the Canal Boats Acts, Factories and Workshops, Slaughter-houses, Baths and Washhouses, the Duties of Sanitary Authorities and their Officers, and Port Sanitary Authorities. The Acts referring to vaccination are fully dealt with, the duties of parents, the public, the guardians, the public vaccinator and vaccination officer in regard to them being ably analysed.

Under Part IX. of the volume before us the law concerning public health in London is discussed, and, although the author professes to provide only a general outline of the very complicated system of sanitary administration at present appertaining to the metropolis, he has certainly succeeded in conveying to the reader a capital idea of the public health functions of the several bodies having jurisdiction in London, and more especially is this the case in connexion with the powers of the London County Council. In those portions of the volume relating to Ireland

and Scotland a very clear conception is given in each case of the several sanitary areas and their governing bodies, which will be most acceptable to those unfamiliar with public health administration outside the limits of England and Wales; and although the Public Health Acts in force in Ireland and Scotland are not dealt with in such detail as those in force in England and Wales, they are so compared and contrasted with the English Acts as to enable the reader to obtain a good grasp of the main provisions in each case.

In the matter of Scotland the reader will bear in mind that the Local Government Bill, 1894, has become law since the book was written. In conclusion, we have no hesitation in saying that Volume III. of this treatise on Hygiene and Public Health supplies a long felt want among medical officers of health.

Enlargement of the Prostate: its Treatment and Radical Cure.
By C. W. MANSSELL MOULLIN, M.A., M.D. Oxon, F.R.C.S.
London: H. K. Lewis. 1894. Pp. 176.

IN 1892 Mr. Mansell Moullin took as his subject for the Hunterian Lectures at the Royal College of Surgeons the Operative Treatment of Enlargement of the Prostate, and in the present volume he has discussed fully the causes, effects, and treatment of the same condition. In the earlier chapters the author treats of the normal structure and function of the prostate, and then proceeds to consider the etiology of enlargement of the gland; and after citing the views of various authorities he concludes that in the present state of our knowledge no satisfactory cause can be assigned to it. Mr. Moullin believes that the enlargement commences as a rule at a much earlier age and occurs much more frequently than is usually imagined, but that in a very small number only is the enlargement of such a form as to interfere with the due emptying of the bladder. The severe consequences which may follow from the obstruction offered to the outflow of urine by an enlarged prostate have long been recognised, yet it is only comparatively recently that any treatment more drastic than the systematic use of the catheter has been recommended. In 1856, indeed, Mercier in Paris devised and employed an instrument for removing portions of an enlarged prostate per urethram, yet the method met with but scanty recognition. Even the most earnest advocates of the habitual employment of a catheter for difficulty in micturition due to enlargement of the prostate must acknowledge that dangers attend its use. It is no easy matter for a surgeon even to be able to guarantee the perfect asepsis of the contents of the bladder in a case where a catheter has frequently to be introduced, however careful he may be of the asepsis of his instruments, and the dangers are increased manifold when the subject of an enlarged prostate is himself entrusted with the use of the catheter. Many cases do well in spite of the risk, but in a large majority the secondary affections of the kidneys sooner or later lead to a fatal issue; so that there is no need for surprise that efforts have been made to permanently cure the condition rather than have recourse to a method such as catheterism, which is merely palliative in itself, and so often productive of serious results. The earlier methods, such as those of Mercier already mentioned, never met with much success, though attempts have been made at intervals to reintroduce what are practically mere modifications of his method. Drainage through the perineum, with or without partial prostatectomy, does not now receive the support accorded to it a few years ago, though it is capable in many cases of almost completely relieving the obstruction to the outflow of urine. The supra-pubic operation, which is of most recent introduction, offers advantages which are not to be found in any of the other methods, and the results hitherto obtained, if confirmed by future experience, will suffice to

place this procedure in the front rank of operative methods for the treatment of enlargement of the prostate.

Mr. Moullin has given an excellent account of the various methods of operation, and has quoted the opinions of others in support of his views. He is inclined to favour, on the whole, for slight cases of enlargement with but a small amount of residual urine, the use of the catheter; but he forcibly insists on the importance of not trusting to the catheter when there is any difficulty in its introduction, when the bladder wall is beginning to lose its muscular power, when the quantity of residual urine continues to increase, or when there is evidence that the kidneys are becoming affected. In such cases he is inclined to recommend the supra-pubic operation, sometimes associated with a perineal incision, unless the condition of the patient is so grave that nothing more severe than drainage can be attempted. Mr. Moullin attaches great importance to the view that the prostate is purely sexual in function, and he speaks not unfavourably of castration as a treatment of the enlarged gland, as the atrophy which follows this operation seems to be both rapid and complete, and he suggests that it should be performed in the worst cases when everything else has failed. At the present time the number of cases in which castration has been done for this purpose, though they were apparently very successful, is not sufficiently large to enable a decided opinion to be formed as to its ultimate value. Mr. Mansell Moullin's work may be taken as a readable exposition of the present state of surgical knowledge with respect to enlargement of the prostate.

The Practice of Medicine. By M. CHARTERIS, M.D. Edin.
Seventh Edition. London: J. & A. Churchill. 1894.

THAT this compendious manual is much in favour with the student is evidenced by the rapidity with which one edition succeeds another, nor is the cause of this popularity far to seek. Covering the whole range of medicine the author has succeeded in giving terse and accurate descriptions of every disease, and has not failed to indicate clearly the main lines of treatment. Naturally his little book has grown in size since its first appearance, but in spite of this it still remains as a good example of the *multum in parvo*. Of the quality of the book we have often spoken, for we consider that it admirably fulfils its purpose, which we take to be that of an introduction to the more extended study of the subject. A student has, under prevailing regulations of the curriculum, at least three years to devote to systematic study of medicine, and therefore he would be well advised to commence his course of reading with a small trustworthy manual like this of Dr. Charteris before proceeding to assimilate the substance of more ambitious text-books. Such manuals as this should then supplement rather than replace the larger treatises. The present edition contains a notice of pathogenic micro-organisms, a proof of the fundamental importance of bacteriology to medicine. The notice, however, is limited to five pages, and although illustrated by a coloured plate can hardly be said to more than touch the fringe of the subject. It seems to us to be somewhat premature in an elementary work of this class to allude to a subject at present so undetermined as that of the existence of sporozoa in cancer.

Method of Operating for Cataract and Secondary Impairments of Vision, with the Results of Five Hundred Cases.
By Surgeon-Captain G. H. FINK, Her Majesty's Indian Medical Service. pp. 77. With Illustrations. London: J. & A. Churchill. 1894.

THE author of this little book has had large experience in performing the operation for the extraction of cataract in India—larger, indeed, than falls to the lot of metropolitan

surgeons even in considerable practice. He describes his method of operation, one of the points in which—the cutting short of the eyelashes—is not commonly resorted to in this country; and he uses both the solution of mercury bichloride containing one part in 5000 and the solution of cocaine, a proceeding that is sometimes thought to be rather dangerous, since it easily leads to detachment of the corneal epithelium; and he employs a special form of speculum in which the resistance of the orbicularis is opposed and overcome by easily applied weights. He tries to remove the lens without pricking or lacerating the capsule. The technique of the operation does not otherwise differ from that in common use, and he employs an antiseptic plastic as a dressing. He adds: "If complications arise they must be treated promptly *secundum artem*," which is good advice, but requires some details to make it useful in practice. The author gives a tabular statement of 500 cases of linear extraction with iridectomy, with results that are astonishing, the numbers being—successes, 453 = 90.6 per cent; accidents and complications, 33 = 6.6 per cent.; and loss by suppuration, 14 = 2.8 per cent. The only question here is what is meant by "cured" and "success." It would have been more satisfactory if the author had given the visual acuteness, after correction with glasses, a month or two after the operation. We notice one case of success in which the vision is stated to have been indistinct, implying that all the rest of the "cured" had good vision. The natives of India seem to be singularly free from most of the secondary complications of cataract extraction.

A Manual of Veterinary Therapeutics and Pharmacology.
By E. WALLIS HOARE, F.R.C.V.S. London: Baillière, Tindall, and Cox.

THIS work appears to be a very important addition to veterinary literature, for although books on the subject are by no means rare, yet none, perhaps, present such claims to attention for the novel features it presents or the wide extent of ground it covers. It professes to deal in a concise manner with the subjects of diagnosis and the general symptoms of disease in relation to therapeutics, as well as noticing in a general manner the action and uses of medicinal agents; it also treats of general therapeutics, and in doing so the plan adopted by Dr. Mitchell Bruce in his well-known work on "Materia Medica and Therapeutics"—that of discussing the actions and uses of remedies under the physiological systems of the body—is followed; while an interesting section deals with special therapeutics, the action of drugs being also arranged on Dr. Bruce's plan of discussing their action from their first contact with the tissues to their effects on the various organs and tissues until they become eliminated. Mr. Hoare has performed his work well and, so far as it could be done, thoroughly. The book may be accepted by those who are concerned in treating the diseases of domestic animals as a reliable guide and quite up to date in everything it deals with. Perhaps to many medical men the most attractive portion will be the special chapter on "Anæsthetics" and the Production of Anæsthesia in Animals. The more scientific and skilful veterinary surgeons of the present day resort much more frequently than their predecessors did to the beneficent and merciful employment of anæsthetics, and strongly recommend their use, especially in the more serious operations they have to perform. Mr. Hoare is known to be one of these advocates for anæsthesia, and having had considerable experience in its production in several species of the domestic animals, he may be considered as an authority competent to give a satisfactory opinion. His remarks will be read with interest by those who are anxious to solve some of the serious problems regarding the safe administration of anæsthetics to our own species, and they will probably

lead many to devote renewed attention to the question whether the results of experiments on animals can always be safely applied to mankind. The horse, for instance, it appears, will inhale pure chloroform with impunity, without any admixture of air, until complete anæsthesia has been induced. Hundreds of horses have been so treated without an accident being recorded. The rapidity with which narcotism is produced with only a small expenditure of the drug is the chief advantage found in giving it by means of a bag or a muzzle fitting closely over the lower part of the face. But Mr. Hoare does not approve of this method, and administers it largely mixed with air. The difference between the horse and dog with regard to their toleration for anæsthetics is very remarkable. Veterinary students and practitioners will, we feel sure, welcome this book and find it of much use in their studies and daily avocations.

The Middlesex Hospital Reports. (Reports of the Medical and Surgical Registrars and Pathologists for the Year 1892.) London: H. K. Lewis. 1894.

THE medical report, by Dr. Frank J. Wethered, is arranged, we learn, on a different plan to that of its predecessor. The general table of diseases has been arranged in accordance with the classification recommended in the "Nomenclature of Diseases" of the Royal College of Physicians of London, the table of results is also amplified. Of the total cases under treatment (1509) in the medical wards there was a mortality of 8.79. It is interesting to note that of twenty-six patients under treatment for diphtheria, sixteen died; tracheotomy was performed in fifteen cases. A short statistical report is followed by an abstract of important groups, a list of some cases of interest, and abstracts of exceptional cases, such as beri-beri, empyema, infective endocarditis, &c. The surgical report, by Mr. Leopold Hudson, is arranged as in previous years, the same nomenclature of diseases being employed. The mortality for the year was 10.8 per cent., but exclusive of death from malignant disease 4.4 per cent. There are included in the report a series of brief statistical tables, abstracts of cases of hernia, of perityphilitis, of sixteen cases in which the peritoneal cavity was opened for various purposes, and of twenty-three cases of compound fracture. An appendix comprises a report, in accordance with the resolution of the medical committee, of all cases of laparotomy with removal of uterine appendages: (a) cases in the gynaecological ward—eleven cases with two deaths; and (b) cases in the surgical wards—sixteen with six deaths. The pathological report, by Dr. A. F. Voelcker, has short records of 286 post-mortem examinations, and is preceded by a summary of diseases. This report occupies more than 150 pages, and could easily be condensed, or its form changed, so that it should not take up more than a third the amount of space which is now permitted. It contains valuable material for study and has evidently been carefully compiled.

Guy's Hospital Reports. Edited by Dr. HALE WHITE and Mr. W. H. A. JACOBSON. Vol. I., being Vol. XXXV. of the Third Series. London: J. & A. Churchill.

THE first impression which we obtain from this volume is one of disappointment; for it is not, in a proper sense, a report of the hospital. We want to know the result of the treatment of the patients, in order that we may learn something of the working of this large institution; but there is nothing on the subject. The first part of the work consists of papers by past and present members of the staff and others, most of them excellent and of permanent interest. Dr. S. Wilks contributes The first case of Popliteal Aneurysm treated by Pressure, the account of which is taken from the

notes which he made when dresser to Mr. Aston Key, on Nov. 25th, 1846; Dr. G. H. Savage, Suicide as a Symptom of Mental Disorder; Mr. C. Higgins, Three Cases of Distension of the Frontal Sinus; Mr. Jacobson, Five Cases of Digital Chancres occurring in Medical Men, with Remarks; Dr. E. W. Goodall, Note on the Hæmorrhagic Form of Diphtheria and Scarlet Fever; Mr. A. H. Tubby, the Prognosis of Abscess in Pott's Disease; Dr. James F. Goodhart, Clinical Observations upon Heart Disease; Dr. Thomas Stevenson, Cases illustrating (a) Poisoning by Terechloride of Gold, and (b) Breslau's Second Life Test in Infanticide; Dr. Hale White, the Effect of giving Lævulose and Inulin to Patients suffering from Diabetes Mellitus; Mr. J. H. Targett, Hydatids in Bone; Mr. F. Gowland Hopkins, Five Cases of Pernicious Anæmia, with Determination of the Iron in the Viscera, and some Observations on the Urine; Dr. J. H. Bryant, One Hundred Cases of Hyperpyrexia. The volume terminates as regards contributions to medicine with a list of specimens added to the pathological museum of the hospital during 1893. The illustrations are not numerous, but they are well executed; the paper by Dr. J. H. Bryant, however, is fully illustrated, there being no less than 100 temperature charts. This paper is certainly deserving of special mention, both for the amount of industry shown in its compilation and its usefulness for future reference. Another paper to which these remarks equally apply is the one on Disease of the Duodenum, which contains notes on 334 cases. Additional interest attaches to this issue of the Reports as it contains a general index to the volumes from one to fifty, including the years 1836 to 1893.

Analytical Records

FROM

THE LANCET LABORATORY.

1. SOMATOSE. 2. EUROPHEN.

FRIED. BAYER AND CO., ELBERFELD; BRUCE AND RUMPF, 15, FISH-STREET-HILL, LONDON, E.C.)

THE name "somatose," according to our examination of the substance to which it is applied, may be regarded as a substitute for albumose, and is derived, we suppose, from the Greek word *soma*, signifying the body. The preparation consists substantially of about equal quantities of deuto- and hetero-albumose, with mere traces only of peptone. It yields a nearly clear and almost tasteless solution, which responds to all the known tests which distinguish albumose from true peptone. A saturated solution of ammonium sulphate throws down practically the whole of the proteids from the aqueous solution. Analysis gave the following results: moisture, 11.50 per cent.; solid matter, 88.50 per cent.; albumose, calculated on 12.30 per cent. nitrogen, 77.49 per cent.; mineral matters, 5.00 per cent. It may be remarked that, although the amount of mineral matter is high, yet it contains a disappointing proportion of soluble phosphate—less than half per cent. of the whole substance—the bulk of it consisting of alkaline carbonates. Nevertheless, we think somatose is a valuable nutritive agent and may be employed with unquestionable advantage as a food adjuvant. It is, of course, especially indicated in impaired digestive function, and its completely neutral taste is an important and noteworthy characteristic.

From the same firm we have received a specimen of "europphen," which is an iodoform substitute stated to possess antiseptic and healing properties superior to those of that body. Chemically it is an iodide of iso-butyl-alcohol obtained by acting on a solution of ortho-iso-butyl-alcohol with a potassium iodide solution of iodine, and is insoluble in water, but freely soluble in alcohol. It contains 27.6 per cent. of

iodine, with which it readily parts company. It is a fine, yellow powder, practically odourless and non-poisonous. In the case of a long-neglected sore, one-half of which was dressed with iodoform and the other half (the worst) with europphen, the latter—so Dr. Nolda¹ states—was firmly cicatrised fully two days earlier than the former. These results are so promising as to merit extensive trial of this interesting derivative by the profession in this country.

CALIFORNIAN WINES (SOLIS BRAND).

(HAGUE, SMITH, & CO., 6, DICKINSON-STREET, MANCHESTER; AND GILROY, CALIFORNIA.)

California, or the Golden State as it is called, is now becoming widely known as a country where the fruits of the earth grow luxuriously and abundantly. It possesses a comparatively virgin soil, yet already the culture of the more delicate fruits—as, for example, the grape—is meeting with distinct success, judging from the excellent qualities of the wines produced there. We have recently had samples submitted to us from the Solis Wine Company, of Gilroy, for examination and analysis. Three types were chosen for this purpose. Side by side with the analytical results obtained they are as follows:—Solis burgundy: absolute alcohol by weight 11.23 per cent., by volume 13.90 per cent., being equal to proof spirit 24.36 per cent.; sugar, 0.15 per cent.; total acidity reckoned as tartaric acid, 0.76 per cent.; extractives, 3.98 per cent.; mineral matters, 0.30 per cent. Solis claret: absolute alcohol by weight 10 per cent., by volume 12.40 per cent., being equal to proof spirit, 21.73 per cent.; sugar, 0.14 per cent.; total acidity calculated as tartaric acid, 0.69 per cent.; extractives, 2.63 per cent.; mineral matters, 0.30 per cent. Solis Hermitage: absolute alcohol by weight 10.92 per cent., by volume 13.52 per cent., being equal to proof spirit 23.70 per cent.; sugar, 0.14 per cent.; total acidity reckoned as tartaric acid, 0.57 per cent.; extractives, 2.53 per cent.; mineral matters, 0.23 per cent. Apart from the satisfactory taste which each wine exhibits, it will be seen that they are free from an excessive amount of free acid constituents, while the sugar is practically nil. The burgundy is a fine full-bodied wine of strong grape flavour; the claret is a similar wine, but of medium character; and the Hermitage is a wine of a lighter kind, well suited for table use. It is satisfactory that wholesome wines like these, which compare favourably with older-established produce, can be obtained at really reasonable prices.

VI-COCOA.

(JAMES EGGO, BIRMINGHAM; AND 6, SOUTHGATE-ROAD, WOOD-GREEN, LONDON, N.)

If chemical analysis is worth anything in indicating the nutritive and tonic value of a preparation, then the above must be assigned a place in the front rank of really valuable foods, since it is the embodiment of the numerous principles contained in malt, hops, kola, and cocoa. While this is partly evident to the taste, further and stronger confirmation of the statement is afforded in the fact that we succeeded in extracting and recognising a tolerable crop of caffeine crystals. Vi-cocoa is, however, the conception of a medical practitioner, who (we quote an accompanying leaflet), "because of his professional duties, has disposed of the recipe to," &c. We are prepared to allow that this preparation is probably of distinct value as a restorative and stimulating food, but we regret to find that a member of the medical profession has lent his name to an enterprise of this kind.

UNSWEETENED CONDENSED MILK: "FIRST SWISS BRAND."

(FIRST SWISS ALPINE MILK EXPORTING CO., 17 AND 18, ST. DUNSTON'S HILL, E.C.)

That the reproach which is so often levelled against concentrated milks—i.e., that they are so frequently deficient in

¹ Therapeutische Monatshefte, October, 1891.

fatty constituents, is not applicable in the present instance is evident from the result of our analysis. Thus the composition of the condensed milk was found to be as follows: total solids, 37.65 per cent.; fat, 9.00 per cent.; mineral matters, 2.10 per cent.; water, 62.35 per cent.; while on diluting it with two and a half volumes of water a liquid giving the following composition was obtained: total solids, 15.06 per cent.; fat, 3.60 per cent.; mineral matters, 0.84 per cent.; water, 84.94 per cent. This corresponds with ordinary cow's milk of excellent quality. The sample was free from objectionable preservatives and added sugar, while no metallic contamination could be traced. So long as these excellent qualities are maintained the milk may be freely recommended for infant and invalid use as well as for ordinary purposes. We read with surprise—as others will—the statement of Mr. Goodfellow, contained in his report on this brand, to the effect that cane sugar “gives an excess of carbonaceous material *very harmful to the body.*”

OVALINE SOAP AND OTHER TOILET PREPARATIONS, MADE FROM YELK OF EGG.

(THE OVALINE SOAP CO., 52, KING-STREET, REGENT-STREET, S.W.)

It is well known that the chief proximate constituents of yolk of egg are vitelline (a peculiar proteid substance), nearly 15 per cent.; of fats (olein and palmatine), besides cholesterine and lecithin, an organic compound containing phosphorus, and a yellow colouring matter. The toilet preparations referred to above (ovaline hair-wash, shaving-cream, ointment, &c.), which are said to be prepared with yolk of egg, should therefore give some indication of the substances just enumerated. The evidence of these in ovaline soap is conclusive. Thus a strong solution of it yields, on boiling, several albuminous flocks, and a silver coin placed in the solution blackens on prolonged immersion from the phosphorus compounds present. Still further corroboration is afforded in the fact that the mineral matter obtained by incinerating the soap was found to contain phosphoric acid—an entirely foreign constituent in the ash of ordinary soap. Apart from the fact that the soap employed is of excellent quality, being free from excess of alkali and moisture, the presence of a definite proportion of fresh yolk of egg probably endows it with properties peculiarly agreeable and salutary to the skin, since not only is this addition calculated to give the latter a beneficial protective influence, but, by reason of the presence also of the easily saponifiable egg fats, protection against the injurious action which some soaps, by the chance excess of alkali contained in them, will occasionally produce on very delicate skins is doubtless to some extent secured. In the other preparations made with the same material we obtained similar evidence of the presence of the principles of yolk-of-egg, which may be regarded as serving a like end.

VIKING CONDENSED UNSWEETENED MILK.

(THE NORWEGIAN MILK CONDENSING COMPANY, LIMITED, CHRISTIANIA, NORWAY; AND BOTOLPH HOUSE, EASTCHEAP, LONDON, E.C.)

It is satisfactory to be able to confirm, in practically every particular, from the results of an independent examination, the claims made in regard to this concentrated milk. Thus our analysis agrees substantially with that already advertised concerning it. The results were as follows: total solids, 32.43 per cent.; fat, 9.00 per cent.; mineral matters, 1.89 per cent.; water, 67.57 per cent. On mixing one part of the milk with two and a half parts of water the resulting mixture exhibits the following composition: total solids, 12.97 per cent.; fat, 3.60 per cent.; mineral matters, 0.75 per cent.; water, 87.03 per cent. This accords with the composition of cow's milk of excellent quality, containing, it is satisfactory to add, the normal proportion of fat. It is preserved without, and is free also from, objectionable matters and metallic impurities. While we concede its undoubted value in infant feeding, it is obviously also well adapted for export and travelling purposes.]

New Inventions.

A TAP REGULATOR FOR GAS FIRES.

THE tendency of atmospheric burners to “light back” was one of the principal defects attached to gas fires, which was pointed out in the report of THE LANCET Special Analytical Sanitary Commission on Smoke Prevention and Perfect Combustion (III. Gaseous Fuel, Gas Heating, and Gas-cooking Appliances).¹ Since the appearance of this report we have had occasion to describe several burners which have been designed to prevent this occurrence, but obviously there is then a danger of running the gas at too low a pressure, so that, although lighting back may be prevented, the flames are easily extinguished on the slightest draught, in which case coal gas would escape unburnt. Moreover, if the flame were turned so low as to be near extinction point, the heating effect on the “fuel” would be practically nil, which would therefore fail to relight the gas when once blown out. To obviate the possibility of such an occurrence some means are required which will automatically restrict the use of the burner to, and within the extremes of, a range of heating power which is at once useful and safe.

One method of effecting this object is by a compound tap such as is described and figured below. It consists of two

taps (large and small), the former of which regulates the range of heat-giving power between the maximum and minimum, and the latter admits the minimum supply which is compatible with usefulness and safety. The taps are so arranged relatively to each other that on opening the large and main tap the “cam” on its plug acts on the lever of, and opens, the small or bye-pass tap, and when the large tap is “full on” the bye-pass is also “full on” and is locked so as to be immovable. During all subsequent regulations of the supply by the main tap the bye-pass remains open “full on,” supplying a minimum amount of gas, below which it is neither useful nor safe to go—say a supply equivalent to between 0.2 and 0.3 in. One main feature of the device is that the automatic opening and locking of the bye-pass prevent a forgetful or ignorant servant from either failing to open the bye-pass or attempting to regulate by it. A separate movement of each tap is necessary to extinguish the fire.

The manufacturers and sole licensees of this useful contrivance are Messrs. Richmond and Co., Limited, of Warrington, who are supplying them gratis with their “Majestic” Fires.

¹ THE LANCET, Nov. 25th, 1893.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 2, 1895.

IN many departments of medicine the powers of diagnosis possessed by the physician have far outstripped the means of treatment at his disposal; and this is what might have been expected, for the signs and symptoms on which the diagnosis depends are, in the main, the result of comparatively simple laws of chemistry and physics, but the treatment depends in a much greater degree on the more highly complex laws of life itself. Occasionally, however, it has happened that our power of remedying a morbid condition—especially by operation—surpasses our power of diagnosing with certainty its presence, and the question then arises, What degree of certainty should be required before proceeding to operate? The answer to this question must obviously depend on the severity of the operative treatment as compared with the danger from the disease.

We have had the great pleasure to be able in recent numbers of *THE LANCET*¹ to present to our readers an address by Professor AUGUSTO MURRI, delivered before the Lombard Medical Association, who deals with the question in a manner whose fresh and learned originality must, we are certain, have been generally patent. In this address he points out that, while in many cases an acute abscess of the brain may be diagnosed with some certainty, a chronic cerebral abscess may exist and yet may give no positive indication of its presence. Too often the condition is only discovered by post-mortem examination. The diagnostic indications of a chronic abscess of the brain are few and untrustworthy. In the place of first importance among such indications is the presence of a sufficient cause, such as middle-ear disease, local injury, or caries of the cranial bones. Not that the exciting cause need be so grave as these; the abscess may follow any of the specific fevers, and as these occur so very frequently without leaving any such sequela the connexion may not be recognised. The signs which a chronic cerebral abscess may present are few in number—pyrexia, headache, and optic neuritis, but none of these can be depended on: pyrexia is often completely absent, and, as Professor MURRI points out, in many cases a subnormal temperature is present; the headache, if localised and persistent, and occurring after one of the usual exciting causes, is suggestive, but nothing more; and optic neuritis may equally be a sign of a tumour or meningitis. Other symptoms, such as paralysis, though often of use in determining the situation of a lesion, are of no value in deciding as to its nature. If we have in any case a sufficient cause, and the signs already mentioned are well marked, we may be fairly confident that an abscess is present, but we cannot be at all certain. Several of the extremely interesting cases with which Professor MURRI has illustrated his paper demonstrate this most definitely; all the usual indications of a chronic cerebral abscess have been present, and yet

at the necropsy some other lesion has been found. Yet the disease is one most dangerous to life, and if timely surgical aid is not afforded death must result. Under these circumstances what should be done? Shall we wait until symptoms arise which will definitely satisfy us that an abscess is present? If so, it will in a large majority of cases be too late to operate; the abscess will have extended and have ruptured either on to the surface of the brain or into one of the ventricles. The surgeon is on the horns of a dilemma: if he operates before he is certain of the presence of an abscess he may find some other lesion for which he can do nothing; and if, on the other hand, he waits until he is sure of his diagnosis the delay may prove fatal to the patient. The decision must depend on the amount of danger connected with the operation itself. A very similar case is to be found in many abdominal conditions where, an exact diagnosis being impossible and the danger to the patient great, it is now customary to perform an exploratory laparotomy. If, then, exploratory trephining is in itself as little dangerous as exploratory laparotomy, it is obviously the duty of the surgeon, notwithstanding the weakness of the diagnosis, to attempt to discover and cure the morbid condition by opening the skull. With complete antiseptic precautions the operation itself, if carefully performed, is practically free from risk, and it is seldom indeed that it is followed by any disastrous effects.

It is a plea for greater frequency in this operative proceeding that forms the text of Professor MURRI's admirable contributions to our columns. The tendency at the present time among Continental surgeons is to await a certain diagnosis, with an eminently unsatisfactory result, for the statistics show that waiting for more data means waiting for more deaths, as by the time the diagnosis is certain the patient is dying. It may be that in the future some diagnostic method will be discovered whereby the nature of an intracranial lesion may be determined with the same certainty that we diagnose the nature of an intrathoracic condition; but that time is not yet, and at present the surgeon has to decide the question whether he shall leave a patient with a chronic cerebral abscess to die unaided, or whether, even though the diagnosis may be far from certain, he will by operative interference, undertaken with a reasonable chance of success, make an attempt to relieve the sufferer. It is in no spirit of reckless interference, but with well-reasoned sense, that Professor MURRI urges upon his professional colleagues the not infrequent necessity for the bolder measure; and we note with pleasure his compliment to British surgeons, whose records have shown exploratory measures to be frequently attended with exceedingly satisfactory results.

IN connexion with the publication of Surgeon-Colonel HARVEY's presidential address at the inauguration of the Indian Medical Congress at Calcutta we recently adverted to some questions in which, apart from what may be termed the medico-social aspects of such a Congress, Eastern and Western civilisation were alike interested, and concerning the elucidation of which the discussions at such a Congress

¹ THE LANCET, JAN. 5th, 12th, and 26th, and in the present issue.

might fairly be expected to render invaluable aid. Some of these were questions of fact, some questions of theory. There are also questions constantly arising in scientific medicine—of a clinical, bacteriological, and practical nature—which may be said to have assumed everywhere a new aspect when tested and considered in the light and by the aid of methods of modern medical research.

The subject of tropical life, its diseases and their sequelae, is not one of scientific or medical interest merely. It is full of practical everyday interest—to our own country in particular, for we are in constant communication with India and the colonies, with the result that many of the inhabitants of the British Empire are often being subjected to the influence of changes of climate. Professor VIRCHOW, in his address at the Congress of German Naturalists and Physicians at Strasburg in 1885, called attention to a sphere of research in which, he alleged, that neither the English nor the French had hitherto accomplished anything of importance—namely, the modifications of the organism, and particularly of the special alterations of each organ, connected with the phenomena of acclimatisation.

There is probably no country in the world where disease and death-rates are liable to such great fluctuations as India, according as epidemics are present or absent. The amount of labour that has been expended upon the natural history of these epidemics and upon the accumulation of a number of details, converging in certain definite directions according to the views advocated by authorities at different times, has been enormous. The geography, statistics, meteorology, food-supply, and climatic and local conditions prevalent at the time of an outbreak of epidemic disease have all been again and again patiently and laboriously worked out, without our being really any nearer the root of the matter, however, as regards the discovery of the true cause. The very multiplicity of the conditions and phenomena investigated proved most embarrassing, for it was often difficult or impossible to determine and select those which were really relevant to the inquiry, and however important or interesting in themselves they failed to be fruitful, mainly because they lacked precision and did not fall in with the inductive spirit of modern experimental science. All such investigations require to be supplemented and complemented by inductive and experimental methods of research and observation. Whether we must in future look to micro-pathology alone remains to be seen, but it is certain that no search for the causes of disease can be deemed adequate or complete where bacteriological investigations are excluded.

Surgeon-Lieutenant-Colonel CROMBIE concluded his excellent address as president of the Medical Section of the Congress on the fevers of India with an appeal to his medical hearers in Calcutta not to allow France and Germany to remain in the van of bacteriological research, but to make a more careful study of the cases which came under their observation in India. As the Sanitary Commissioner with the Government of India remarked in one of his late annual reports, what is wanted in India is not more private work, however enthusiastic, but work by trained experts in properly equipped laboratories to supplement the clinical work of medical officers. THE LANCET has frequently urged the need of this, as also some

organisation for the prompt investigation of outbreaks of disease at the time of these occurrences and while facts are still fresh in the minds of local observers, to be followed by such local remedial measures of a sanitary nature as are apparently required, either at once or after fuller investigation and report. In this way scientific and practical work would go hand-in-hand, and some real progress would be made. India presents a rich field for investigations of this nature. The fact that KOCH's comma bacillus, for example, is present in cases of cholera may be taken as established; but its causal connexion with cholera has, in the opinion of many, still to be demonstrated as an adequate explanation of all the phenomena of that disease as it comports itself in Indian experience. Again, Surgeon-Lieutenant-Colonel CROMBIE is a convert to the amoebic theory of malarial fever, and says that, although there are some striking points of contrast between the order of frequency of intermittent fevers in India as compared with other countries—the Roman Campagna, for example—still, wherever malarial fever is found to exist—in America, Africa, Asia, and Europe, and in localities differing from each other in every particular of climate—the essential phenomena remain the same, and LAVERAN's micro-organism is discoverable in the blood. Under such circumstances it seemed to him to be impossible to offer any longer a reasonable resistance to LAVERAN's theory of its causation. As regards the remittent fevers met with in India and semi-tropical climates some are attributable to malaria and some are not, and it is obviously of much practical importance that these should be differentiated, the one from the other, for quinine and arsenic are the proper remedies in the one case and inefficacious, if not actually injurious, in the other. Nor are all the cases of a continued non-malarious form of fever encountered in India and elsewhere clinically identical with typhoid fever. There is, moreover, a great deal still to be worked out in regard to this particular fever in India. Why should typhoid fever be so frequently and disproportionately present among our young European officers and soldiers during their earlier years of service in that country as compared with the natives? Is the typhoid bacillus of EBERTH and GAFFKY to be found in all the cases of typhoid fever met with in India, because the discovery of this bacillus would serve to distinguish the nature of the fever and stamp its identity with the typhoid fever of other countries? These and many other questions in Eastern medicine and pathology are still awaiting solution, and India affords a wide field for their investigation by the aid of modern methods and appliances of pathological and bacteriological research. Nor can it be denied that these are matters of urgent practical importance, for the loss of life and sickness caused by typhoid fever—to take only one example—among the young manhood of the British army in India amount to a terrible total annually.

Surgeon-Major DIMMOCK, Professor of Midwifery, Grant Medical College, Bombay, in his address to the Obstetrical and Gynaecological Section of the Congress, discussed the causes and effects of puerperal fever in India, and showed how in that country we are confronted with conditions of climate, season, race, habits, and environment, and not alone with special disease entities. SEMMELWEISS long ago put us in possession of the axioms of puerperal fever and

its relation to puerperal infective septicaemia. Professor DIMMOCK has extended his inquiries into the different forms of fever met with in the pregnant or puerperal woman in India. Mr. WEATHERLY, moreover, has related in a paper read before the same section of the Congress the results of his experience in Africa, Florida, and India in regard to the influence of malaria in abortion and sterility.

EXCEPTION may be taken to the title of a pamphlet we have received from Dr. ARTHUR RANSOME—namely, "The Consumption Scare,"—but without entering fully into the question of whether there is or is not a "scare" we can say with truth that there exists a tendency to attribute to pulmonary phthisis a much more gravely infectious nature than it is proved to possess. Dr. RANSOME quotes from a paper issued by a society of medical officers of health, setting forth with elaborate detail the way in which phthisis is spread by the dust of dried sputa, and adding directions as to disinfection, cleanliness, and similar precautions; but, as he rightly remarks, nothing is said therein about the security given by these means. Secondly, he quotes a paper by Dr. ARNOLD CHAPLIN on the Necessity for placing Tubercular Phthisis under Control, which paper contains some stringent regulations for segregation.

Let us try to picture what this drastic treatment of phthisis would mean to the sufferers by recalling the condition of the leper so recently as the seventeenth century. In the seventeenth century leprosy was the awful and abiding scourge of the peoples of Greece and the Aegean Islands. It was known to be infectious, and the means for the prevention of the spread of the disease were carried out to their logical end. The island of Leros, with the exception of one or two villages on the coast, was entirely given up to lepers. The territory they inhabited was called the "Desert of St. Cosmas." Communication with the rest of the island was entirely cut off by natural obstacles, as rocks and rivers, and where these failed by walls. There were two lines of fortification, so to speak, surrounding the desert. Inside the first strangers might go twice a year and return after holding converse with the inmates; inside the second, if anyone went, return was absolutely prohibited. Children, and there were many such born in the desert, were never permitted to leave it; at their death they were buried within the precincts. The lepers were ministered to by Basilian nuns and priests, who voluntarily undertook the duty. These also, once they had passed the second gate, never came out again. The system was undoubtedly effectual against the evil, and, moreover, was only logical. If segregation is to be of any use in a disease it must be complete, uncompromising, ruthless. (We are using the term segregation in its strictest meaning, and do not intend to overlook the benefits clearly to be derived from systems of notification properly worked. These are not segregation at all, and have not been suggested as of possible use in the prevention of phthisis.) To make minor attempts at secluding the infectious sufferers is to play at preventive medicine. Without debating the question further, does anyone imagine that our knowledge of phthisis warrants the recommendation of such measures towards the phthisical? Yet if segregation

is to be really useful, the Isle of Wight, say, should be transformed into an Isle of Leros.

The idea that phthisis is an infectious disease is an old one in the south of Europe, but of comparatively recent date in this country or in France and Germany. Dr. WILLIAM BUDD, in our columns (as early as 1867), was the first observer in England to make the suggestion that phthisis is a true zymotic disease, that the tuberculous matter is itself (or includes) the specific morbid material by which the disease is propagated from one person to another, and that by the destruction of this matter on its issue from the body, seconded by good sanitary conditions, may hope to rid ourselves of this scourge. These views met with but little favour at the time, and "it was not until after KOCH's great discovery of the essential organism of tubercle that any idea of serious danger occurred to the medical mind." It is not with any intention of saying, we presume, that no source of danger exists from infectivity in phthisis that Dr. RANSOME has written this pamphlet, but rather to show that infectivity has lately gained too much prominence, and the influence of pure air and light, especially sunshine, as the preventive and curative measures provided by nature proportionately belittled. In some experiments carried out by Dr. RANSOME and Professor DELÉPINE an exposure of dried sputum from tuberculous patients to sunlight for one hour entirely destroyed the bacilli, so that guinea-pigs—animals most susceptible to tubercle—were quite unaffected after being inoculated with the same. Specimens of the same tuberculous dust gave tubercle to guinea-pigs after being kept in the dark with little air for thirty-five days. That light and air are two potent preventive agents these experiments would tend to show, and we recommend them to the consideration of those who are concerned in the construction of our new buildings.

Annotations.

"Ne quid nimis."

WORKHOUSE ADMINISTRATION AS AFFECTING THE SICK.

WE noted in the last issue of THE LANCET an example of delay, which proved fatal, in the case of an aged inmate of the Stepney Workhouse, and remarked upon the many imperfections which still obtain in the arrangements for the care of the sick poor. This week we have received an important circular from the Local Government Board, addressed to the newly elected boards of guardians, dealing with this very subject. The circular deals in a most thorough manner with the duties of the medical officer, lays special stress upon the absolute necessity of a supply of good nurses, and strongly urges that pauper inmates should no longer be allowed to act as assistant nurses, except under special circumstances. The guardians are exhorted to see that due provision is made for nursing by night as well as by day, that all nurses should be adequately remunerated, and that the most careful consideration should be given to any representations made by the medical officer of the workhouse in the discharge of his prescribed duties. There is no reason why the sick poor in workhouses should not be treated as efficiently as they are in hospitals. Of course, the cases for the most part are those of a very chronic nature, but they are none the less distressing to the patients nor do

they need anything less than the most constant attention. The days of workhouse horrors as described by Dickens have, we may hope, passed away for ever; but even now there is need for more of the old spirit which animated the mediæval "bede-houses," when a sick poor man was looked on as the peculiar care of the Church and not, as we fear is in some measure the case now, an extra burden to the long-suffering ratepayer. The question of the relief of the sick poor has always been a matter of deep concern to THE LANCET and its founder. As far back as 1837 the then Home Secretary brought forward a motion, a similar one having been previously given notice of by Mr. Wakley, the ultimate outcome of which was the Poor-law Amendment Act of 1842.

A CASE OF APPARENT DEATH.

WE have received from Dr. R. Mitchell of Bury the following graphic detailed account of the remarkable case of resuscitation which has been so widely commented upon in the press: "Mrs. Sutcliffe of Heap Bridge, Bury, Lancashire," Dr. Mitchell writes, "was a very healthy woman up to the last three years, when she began to suffer from pain at the stomach and sickness with diarrhoea. She gradually got worse and became very emaciated—white and bloodless in appearance. Three or four days before death she on several occasions appeared to be on the point of death, and at these times the friends were all assembled to witness her last moments. On the night of Jan. 16th she was very restless up to midnight, when she asked to be placed on her left side, and all the pillows and bolster to be taken away, and she went into a quiet sleep which lasted till 2.30, then she gradually stretched her arms by her sides and her legs straight down, and became stiff and cold. Her jaw dropped, leaving her mouth open, and the son and nurse placed a little ice in it, but it ran out again. She did not open her eyes, did not breathe, and her heart, which was felt by her son and nurse to slowly beat, gradually ceased in about ten minutes. The nurse, experienced at death-beds, and the son believed her dead. They left her as she lay for one hour and twenty minutes, when they carried her upstairs to a bedroom with the assistance of a woman who had often helped in cases of death before. And these women remarked that the body was very stiff and cold, and that they would just have time to 'wash and lay her out' before she would be too stiff. Arrived in the bedroom, the body was placed on a sheet on the floor, washed, and dressed in the customary dead clothes, and then placed on a bed with a board beneath it. The laying-out was completed by 5 A.M., and during the morning friends frequently went to see the supposed corpse and all aver that there were no signs of life. The undertaker who measured the body for a coffin believed her to be dead. Several who had occasion to touch the body said it was cold and stiff as death. About 10.30 A.M. two women were arranging the chamber when the supposed corpse coughed, the pennies which were on the eyelids fell off and the women ran downstairs in terror and could not be persuaded to go back. Other women went and watched the gradual recovery of the life. The eyes opened without signs of consciousness, the breathing became freer and stronger, and the pulse better. These women say 'she gradually and slowly came round.' I saw her about 1.30 P.M.; she was lying as 'laid out,' her eyelids opened and closed, her breathing was regular and the bedclothes could be seen to rise and fall on the chest, her hands were clasped across the chest, and the pulse was easily felt, soft and regular. She was quite unconscious; the limbs were stiff and cold, possibly due to lying in a cold chamber for eight hours. She was removed to a warm bed, hot bottles were applied, and brandy and warm

water given in small quantities, and in the evening she spoke in whispers, asking to be put in her own bed, and other sayings, which showed her to be conscious. She never made any allusion to the state she was in during the morning and was never conscious before the evening of that day. She gradually became weaker and weaker, and died at 7 A.M. on Jan. 18th, twenty-eight hours after the supposed death, in exactly the same attitude and with exactly the same signs as in the preceding morning. The body was very much worn, and in sleep the face was like that of the dead. She had taken nothing but ice or a little water for days. There was an extensive bed sore slough at the bottom of the spine; it was black and had been exquisitely painful. The above is a true statement of the 'resuscitation of an apparently dead woman' according to the daily papers of the last week. (Signed) R. MITCHELL, M.D." From this account the case seems to have some analogies with the condition sometimes observed in cholera. The patient was obviously reduced to the last stage of asthenia, and the temporary suspension of vital functions, followed after the brief rally by actual death, is not surprising, although no doubt exceptional.

DEATH OF DR. LOMBARD OF GENEVA.

WE regret to have to announce the sudden death on Jan. 22nd of Dr. Lombard of Geneva, the leading medical climatologist in the world. He was born at Geneva in March, 1803, and had therefore nearly completed the great age of ninety-two when, without showing any notable failure of mental power, he passed suddenly away. Up to the last he took a keen interest in medical science and welcomed the reported successes of sero-therapeutics in diphtheria. Dr. Lombard commenced his medical studies at the University of Edinburgh (1822-24), then at the zenith of its fame, but, unable to stand the rigours of a Scotch climate, he passed to Italy, where he at once began to study the subject which favours his great claim to a niche in the Temple of Fame. He completed his medical education in Paris under Andral and Louis, graduating in 1827, his doctorate thesis being on Tubercles. He settled in Geneva in 1829 and gave himself up to hospital and consulting practice and literary labours, the latter resulting in 1856 in the publication of his "Climats de Montagne," of which a third edition appeared in 1873, followed by his monumental "Traité de Climatologie," which was published from 1877 to 1880. Until the age of eighty-three years he continued his scientific and practical labours, and in 1892 presided over the International Congress of Hygiene at Geneva. He was a man of great probity, charity, and full of the truly religious spirit, and was universally esteemed by his fellow townsmen, who were proud of his high reputation. It is interesting to find that Dr. Lombard, amongst his numerous distinctions, was an honorary Fellow of the Medical Society of London.

LEGISLATION ON PENNY ICES.

SIXTEEN years have already elapsed since we denounced the danger involved in the manufacture and sale of penny ices.¹ The colouring material, even when aniline dyes are used, is employed in such minute quantities that this offers no particular danger; but the use of bad milk and bad eggs in extremely unhealthy and filthy localities is a very serious matter. The manufacturers of penny ices are chiefly Italians of the lowest class, and they live crowded together in Italian colonies, the principal one being at Saffron-hill. They inhabit houses owned by a "padrone," who exploits their labour, finds the necessary capital, and is careful not to charge them any rent for their sleeping accommodation. Thus he is not a common lodging-house keeper and escapes

¹ THE LANCET, Aug. 24th, 1878, and Oct. 18th, 1879.

the action of the law. In a padrone's house of this description our commissioners found in the rooms three and four beds; some were occupied by men and women, others by single men or single women; all conditions and sexes living promiscuously together. Some of these Italians were piano-organ men, others traded in penny ices; and these ices were mixed or made on the premises, in the midst of indescribable filth and overcrowding. The milk, the eggs, the cornflour mixture, &c., as we reported at the time, are left standing for hours in the foulest atmosphere, are manipulated by the dirtiest and most unwashed Calabrians, and are mixed—sometimes boiled—in the same saucepans and cauldrons employed to cleanse dirty linen. Of course, in the case of such a population which has no conception of the laws of sanitation, the liability of the contamination of the stock of milk, eggs, and ice creams is a factor by no means to be disregarded. Obviously ices should be made with care and with all the precautions necessary to prevent such contamination. But so long as no supervision is exercised by the authorities the Italian padrone is not likely to indulge in so extravagant a luxury as cleanliness. Fortunately we are now informed that the Local Government Board has written to certain of the metropolitan vestries notifying that a Select Committee will be appointed to inquire into the advisability of instituting legislative action so as to secure the registration of itinerant ice-cream vendors. Thus at last we may hope that something may be done to improve the conditions under which this popular "delicacy," the penny ice, is made.

MEDICAL MEN AND INSANITY IN RELATION TO LAW.

THERE is, perhaps, no subject throughout the whole of medical jurisprudence which offers such difficulties to both medical men and lawyers as insanity. Numbers of both medical and legal text-books on the subject exist, all excellent in their way, but with the grave defect that the medical ones are too technical for the lawyers, and *vice versa*. Nor is it only the members of these two faculties who are in need of a clear and lucid exposition of the subject. Any educated man is liable to have to serve as a special jurymen and to have to decide cases in which insanity may bear a large part. It is because we are sensible of this want in medico-legal literature that we welcome the announcement of a work entitled "The Insane and the Law," written by Percy Smith, M.D., F.R.C.P., Physician at Bethlem Royal Hospital, F. Pitt Lewis, Q.C., and A. J. Hawke, barrister. From an advance sheet of the introductory chapter we learn that the book will deal with the *personal* position of the insane rather than with their property, as do the existing legal works on the subject, while existing medical books treat of the disease as such only; whereas the forthcoming work will try to set out in terms sufficiently plain for the non-medical mind, on the one hand, and the non-legal, on the other, the subjects of—(1) Detection and treatment; (2) maintenance; (3) responsibility, both civil and criminal; and (4) capacity to give evidence as a witness or to make a will. The authors' names are a sufficient guarantee that the book will be written by experts, and we await the appearance of the work with the consciousness that it will supply a long-felt need.

THE COST OF MEDICAL TREATMENT.

THE managing committees of hospitals have reason to think somewhat gravely of the cost of medical treatment. The drug bill, the figured columns relating to surgical necessities, and the order lists of dietetic accessories are as leaden weights upon the heart of their endeavours to benefit mankind. Nor is the general practitioner free from a like source of anxiety, at all events if, guided by the metropolitan

method, he adds to professional skill and labour the generous charity of dispensing medicines to an opulent community. He and others of the oppressed in pocket may, therefore, learn with an interest born of new hope that it is possible, even easy, out of the smallest professional gains to make practice pay and more than pay. Such, at least, is one obvious moral to be derived from certain published statements relating to the Lincoln Oddfellows' Medical Institute. The lodge, it is said, provides for 4889 members. Its receipts for last year amounted to £1155 1s. 4d. Of this sum £500 17s. went in salaries to medical officers &c. £231 for rent and general expenses, and £161 5s. 11d. for drugs, the credit balance being £206 0s. 3d. Prescriptions numbered 31 431, and the drug bill distributed over these consists therefore of components having each an average value of 1½d. This result is certainly very satisfactory in its purely financial aspect. As to whether it represents a relatively high average of medicinal or surgical efficiency we are not so certain. If the panoply of the Oddfellows' attack upon disease consists merely of stock medicines of a simple character, we may well agree that it does; but it is clear that in such an armament there exists no more than a nominal provision for many weapons of proved quality, to which our present modes of treatment owe much of their mastery. We fully recognise the value of economy, especially as applied in the medical practice of charitable institutions. It is evident that the Lincoln Oddfellows, and many other like associations, share our views on this matter. At the same time, we should like to be assured that they have not, with regard to it, bettered the suggestions of business prudence after the manner familiar to some parochial authorities. An expenditure so trifling as 1½d. on each prescription seems hardly compatible with power and effect in dealing with the varied and often dangerous phases of disease.

CLINICAL OBSERVATIONS ON WILD BEASTS.

THE *Bristol Medico-Chirurgical Journal* for December contains a remarkable paper by Dr. A. J. Harrison, in which he embodies some of the more striking events in connexion with a branch of practice of which few have much experience—that of physician to the inmates of a Zoological Gardens. The "tiger and ape" that lie dormant in every man's nature and occasionally get loose and secure for their late host the notice of a police magistrate are here found in plain, unvarnished form as one would expect, and Dr. Harrison mentions several crimes of violence committed by the animals under the influence of jealousy or sexual excitement. But what we should not expect to find is so much similarity among the cases related to the diseases and accidents most familiar in human experience. Intussusception, pericarditis, empyema, phthisis, Pott's paraplegia, cancer, ingrowing toe-nail, and ruptured uterus are examples of what we mean, and they serve to remind us that the gulf on the physical side between man and the brute is not so wide as might be imagined. Dr. Harrison's most interesting patients were, fitly enough, the lions. The first monarch, Hannibal by name, was found dead in his cage, the cause of death being hæmorrhage due to rupture of an enormously enlarged spleen which weighed twenty-one pounds and a half, at least twenty times the normal weight. Just sixteen weeks later (the average period of gestation in the lioness) his widow was confined of twins, both of whom subsequently had an interesting medical history. One, a lioness, had a prolonged labour and died from a ruptured uterus, an accident which Dr. Harrison has also known to occur in a cheetah. The other twin—a lion—was for many years an ornament to the Gardens, and died from "senile decay," but in his youth he suffered from an ingrowing toe-nail, which caused him so much suffering that its removal was necessitated. Chloroform is badly taken by these larger carnivora,

according to Dr. Harrison, causing much excitement and struggling, and other expedients had to be devised. Ultimately he was coaxed into a smaller travelling cage, and from that he was dislodged into a strong box just large enough to contain him, and, after he was in, in order to diminish his struggling space, large pieces of wood were pushed in to occupy any interstices. After violent struggles, which often caused a prudent retreat on the part of spectators, the lion incautiously put his paw through a hole which had been left in the front of the cage. The ingrowing nail was seized with carpenter's pincers, and the patient and the surgeon between them managed to induce the paw to part company with the nail. Immediately the operation was over the lion gave no trouble, and appeared to be as sensible of his surgeon's skill as was the lion of Androcles. Dr. Harrison, like many competent observers, throws great doubt on the theory that the snake "fascinates" his victims. He quotes instances where pigeons and even timid rabbits remained in the cage for several days, the python treating them in a kind and friendly way and caressing them, and then, as soon as time had sufficiently sharpened his appetite, killing his prey in a sudden and treacherous fashion. Regarding the fasting of snakes after gorging their prey he has some interesting observations. Seven or eight months of voluntary fasting have been observed, and one python who ultimately died is said to have lived for eighteen months without taking food, a record that no "fasting man" is ever likely to break.

DEATHS UNDER ANÆSTHETICS.

WE are indebted to the senior house surgeon for a careful account of a recent death under chloroform which took place at the Bristol Royal Infirmary on Jan. 14th. The patient, a woman aged fifty-five, suffering from trismus caused by a carious wisdom tooth, sought for relief and was admitted into the infirmary. On the 14th she was given chloroform after careful examination of her chest. The emphysema of the apices and borders of the lungs and dilatation of the tricuspid orifice revealed by the necropsy were apparently not sufficient to give clinical evidence, as we are told there was nothing abnormal about the chest. Chloroform was the selected anæsthetic, as it was believed nitrous oxide gas or ether would not have overcome the muscular spasm (trismus). Skinner's mask was used. The struggling stage, although violent, was not prolonged, and during it the chloroform was given with due caution. Anæsthesia was induced in four minutes, about three drachms of the anæsthetic having been used. At this time the corneal reflex was absent and the pupils were moderately contracted, the respiration and pulse being normal. The patient was then wheeled into the operating theatre, the transit occupying a few seconds. She was lifted on to the operating table, and respiration was then noticed to have ceased. At this moment slight cyanosis of the face was seen and the radial pulse was observed to be absent. The head and shoulders were pulled over the end of the table, the mouth opened, and the tongue pulled out with forceps, while artificial respiration was practised. The method of cardiac stimulation dependent upon rapid percussion over the heart area was also tried, and as these means failed electrical excitation of the heart was attempted, and finally acupuncture of that viscous was employed. The usual stimulants, nitrite of amyl and enemata, were also called into requisition, but no recovery took place. This unfortunate occurrence seems very difficult of explanation unless we regard it as a paralysis of the medullary centres through what was, not ordinarily speaking, an overdose of the chloroform. Moderately contracted pupils, with soft normal breathing, are hardly consonant with an excessive intake or a retarded output of chloroform. We are acquainted with an almost identical

case which occurred some years ago at a London hospital. The patient was apparently lightly anæsthetised by chloroform, and upon being lifted from the trolley-couch on to the operating-table died at once. In that case it was believed that the movement, acting upon an incompletely anæsthetised person, had in some inexplicable manner initiated an inhibitory impulse to the heart. This explanation may or may not have much weight—at all events, a patient is probably seldom so imperfectly anæsthetised as to be a likely victim to such a state of affairs. We reported a recent death at the Middlesex Hospital which took place from the A.C.E. mixture. We have now been favoured with a further account of the occurrence and place it before our readers. The patient, it will be remembered, was to have been operated upon for suppurating glands in the neck. He was a muscular man of intemperate habits and was admitted into hospital the night before the operation was to have taken place. On Jan. 3rd he was given some freshly prepared A.C.E. mixture from "the ordinary flannel-inhaler" (Skinner's mask). He struggled very violently and had to be restrained. To overcome this a "little chloroform" was sprinkled upon the inhaler and the struggling passed off. The muscular rigidity became less marked in two minutes, the A.C.E. mixture being again given. "A little later" the breathing became shallow and the pupils dilated. The face then became pale and the pulse could not be felt. Respiration then ceased and cyanosis appeared. The usual restorative measures proved abortive. The necropsy showed a dilated right ventricle with fatty infiltration of the myocardium. The left heart was also dilated and fibrotic, the lungs were emphysematous, and the other viscera and brain were congested.

THE WIGAN BOARD OF GUARDIANS AND OUT-DOOR RELIEF.

IN an annotation which appeared in the last issue of THE LANCET we referred to this board in reference to their medical officer's salary, a few of the guardians being anxious to save the rates by attacking his salary. At their last meeting the Local Government Board found fault in respect to their out-door relief, which we mentioned was excessive. Mr. Jenner-Fast, the inspector, apparently did not agree with the medical officer's salary being attacked, but pointed out that the number of cases on the relieving officer's books could not possibly be visited and efficiently inquired into. Medical relief was generally the thin edge of the wedge, and every case should be visited. About £12,000 a year was the amount of out-door relief paid in the Wigan Union. He suggested that additional relieving officers should be appointed in one district of the union alone (Orrell). He found the acreage was 20,038, the population 24,000, and 661 cases on the books; while the total amount paid in out-door relief for the half-year ending last Lady Day was £2128. The Local Government Board believe that 200 cases on a relieving officer's books are quite enough for one officer to look after properly; but he found in No. 1 district 715 cases, in No. 2 district 1000 cases, in No. 3 district 987 cases, in No. 4 district 252 cases, and in No. 5 district 645 cases. Now it is evident either that these numbers cannot be efficiently attended to or that the Local Government Board is wrong as to its estimate. If this newly elected board of guardians wishes to put its house in order and save the rates it will first appoint an efficient staff of relieving officers, for the inspector stated that "he felt sure that many applications for relief were granted which, if thoroughly looked into, would be found to be cases which could manage for themselves, and he could not see that the circumstances of the Wigan Union were so completely different from all the other unions as to necessitate an amount of out-door relief which

was ten times as large as that of most unions." Is it to be wondered at, therefore, that the medical officer's extras are more than in other districts? But before altering the terms on which an officer has been appointed it would be well for the guardians to attack the bigger and graver question. Some guardians, we know, would prefer to underpay their officers and give relief indiscriminately, but such a proceeding is not to be encouraged, for, although it is right and proper to relieve poor and needy persons efficiently, yet there is the moral responsibility not to manufacture permanent paupers. If more relief were given to the needy and less to those who have no title or right to it the rates would be saved and thriftless impostures would disappear.

DIPHTHERIA IN LONDON.

THE Registrar-General is able to record that last week's mortality from diphtheria in London was below the corrected average for the corresponding week of the preceding ten years. True, the deaths were but one below that average, but even so it is pleasing to find them on that side. The deaths registered were 29 in number, a progressive fall from 50 in the week ended Jan. 5th. Of the total, 26 were of persons aged from one to twenty years and 18 were of infants in the first quinquennium of life. Six belonged to Islington, 6 to Poplar, and 2 each to Mile-end Old Town, St. George Southwark, and Greenwich sanitary areas. In Greater London there were 15 deaths, 8 of which occurred in West Ham and 2 each in Croydon and Epping districts.

AN APPEAL FOR A MEDICAL MISSIONARY.

THE Secretary of the Archbishop's Mission to the Assyrian Christians sends us a note on the need of a medical man in this work. Hitherto the Mission has had to depend for medical assistance upon Dr. Cochrane of the American Presbyterian Mission, who has always willingly afforded help. If any young medical man possessed of good health desires a field of interesting work, both from a medical and an ecclesiastical point of view, here is a chance for him. His outfit (in reason) and the expenses of his journey would be paid for him, and all drugs, instruments, &c., would be supplied and would be the property of the Mission. His salary would be £25 a year with board and lodging. This is not, it is true, a large scale of payment, but it is more than most house surgeons receive in London. The Mission field lies on the borders of Turkey and Persia, the climate is pleasant, and a good horse can be bought for £10. The "practice" would include ordinary diseases with sundry local fevers, a good deal of eye work, and general surgery, with a possibility now and then of some military surgery owing to difficulties with the Kurds. Further information can be obtained from Rev. R. M. Blakiston, 7, Dean's-yard, Westminster.

THE MEDICAL DEFENCE UNION.

THE report of the Medical Defence Union for 1894, of which we have been favoured with an early copy, shows that this Union continues to grow in numbers and in usefulness. The somewhat disturbing incidents of the year which led to litigation are fully and frankly detailed in the report and in no degree lessen our sense of the efficiency of the Union for the great purposes which it was created to serve. A schedule of a few (about eighty, not itself a small number) of the cases and applications dealt with by the council in the year illustrates its great value in protecting medical men from unjust attacks, in guiding them in circumstances of perplexity, in averting lawsuits, in reporting to the medical corporations or the General Medical Council cases of unprofessional conduct, in advising in a kindly spirit members who are pursuing wrong methods of practice, in promoting prosecution in fit cases &c., in taking action where members

are attacked unjustly and bringing it to a successful issue, &c. The number of members of the union advances by leaps and bounds; they have risen from 2924 in 1893 to 3358 in 1894, and the guarantee fund has increased from £4150 to £5032. All the work, including the legal expenses of the last year, has been carried out without trenching on the reserve fund. One significant remark in the report is that "blackmailing" cases become less every year, and that in every case brought before the union the prompt action of the council in directing its solicitor to accept service of the threatened writ on behalf of the member has prevented its issue and stopped further proceedings. Mr. Victor Horsley, the President, has attended forty out of forty-two meetings, and displays as much interest in them as if he were the most general and assailed practitioner in the profession. We congratulate him and his staff on the thoroughly satisfactory report of the year.

PUBLICANS AND DEAD BODIES.

A CASE of considerable importance in view of the disposal of dead bodies was heard at the county court of Birmingham on Jan. 23rd, before Mr. John Amphlett, deputy judge. The action was taken by a publican to recover £15 damages from a police sergeant for the annoyance, expense, and loss of business occasioned through the dead body of a woman being deposited in the club-room of the public-house without plaintiff's permission. It appeared that on Saturday, Aug. 8th, 1894, a woman was taken ill outside the plaintiff's house. Plaintiff took her in, gave her brandy, and sent for a medical man; the woman, however, died, and plaintiff had her decently laid out in an outhouse. A police constable was satisfied with the arrangements, but the defendant when he appeared insisted upon the body being taken into the house, and in spite of plaintiff's protest it was carried into the clubroom, where much annoyance was caused. It seems that if there is no public mortuary the responsible person is the churchwarden of the district, upon whom devolves the duty of finding a suitable and decent place for the body. Evidence was given to substantiate the claim, and a verdict for the full amount was given. The power of the police to insist upon a publican finding room for dead bodies is therefore unsupported by legal authority, an action for trespass being the liable outcome of such decision. It also points to the desirability of properly appointed public mortuaries, a consideration for the reflection of the new county councils in the interests of the community. A popular fallacy is dispelled by this judgment and the law made clear and intelligible.

DR. JAMESON ON SOUTH AFRICA.

ON Monday evening, Jan. 28th, Dr. L. S. Jameson, C.B., Administrator of the British Chartered Company's Territories in South Africa, delivered an address before an audience of nearly 2500 people in the great hall of the Imperial Institute. H.R.H. the Prince of Wales presided, and many distinguished persons, representing art, science, the learned professions, and commerce, were present. The past, present, and future of South Africa constituted the subject of Dr. Jameson's address, and with a somewhat nervous though deliberate delivery he briefly sketched the rise and progress of our new South African territory. Starting from a period something more than 300 years ago, when some of the best families of France and Holland were compelled to emigrate and settle down on a narrow strip of land between Table Mountain and the sea, the lecturer traced the history of the colony to the time when the Cape of Good Hope was transferred to the English Crown. From that time to the present Dr. Jameson drew a brief and vivid picture, detailing our troubles with the Boers and the Zulus. In glowing colours he then put before his

audience Rhodesia as it is and its capabilities, expressing his belief that that territory has and will have the greatest effect in producing the future of South Africa—a future which he wished to interpret as the commercial union, amalgamation, and federation of the South African States. Rhodesia, the lecturer said, is a country nearly as large as Europe, a country where white men and women can live and where their children can be reared in health. In minerals and in the products of agriculture the country is rich, and railways, roads, and telegraphs are rapidly opening it up. The picture drawn by Dr. Jameson was of a land veritably flowing with milk and honey, and even if some allowance is made for his high eulogies, still what the lecturer desired to prove seems undeniable—namely, that in our African territory there we have magnificent accommodation for our overflow population.

THE BRITISH INSTITUTE OF PREVENTIVE MEDICINE.

We publish this week the report of the Director of the British Institute of Preventive Medicine. In this is included the reports of the medical superintendents of certain of the fever hospitals under the management of the Metropolitan Asylums Board upon the results of the antitoxin treatment of diphtheria at their several institutions. We have from the beginning felt that so important a departure in treatment, with such high claims and excellent introductions, ought not to be judged lightly or speedily, and that all judgment should be based upon clinical records of series of cases undertaken under special and highly tested conditions. The reporting of isolated cases can, we consider, only be useful when such cases are properly collated for purposes of comparison, and when all the data necessary for making fair comparison are forthcoming.

PRESCRIBING CHEMISTS.

THE question whether it is not only legal but desirable that a person with no medical qualification should prescribe for a patient of whom he knows nothing was forcibly illustrated by a case which came before the St. Pancras Coroner's Court on Jan. 22nd, a brief account of which we give as reported by the *Times*. James Jefferies, aged fifty-eight years, having complained of severe internal pain, his daughter-in-law went to a chemist's and brought back an eight-ounce bottle labeled "The mixture; one tablespoonful to be taken every hour if needful.—J. B. Johnston, 218, Kentish-town-road." The sufferer took a dose at once and was relieved, but at 3 A.M., being again in pain, he took another dose and died. Dr. Sanctuary stated that on making a post-mortem examination he found a large aortic aneurysm which had caused death by pressure on the trachea. In this particular case the action of the chemist probably in no way accelerated the patient's death; but the difficulty of the responsibility of the unqualified prescriber still remains. The poorer classes make no distinction between a "doctor" and a "chemist." They are both people from whom you can get "a bottle" at eightpence or a "pink powder" for twopence. To be perfectly just to an intelligent and upright body of men, it is fair to say that deaths can but rarely be traced to the action of any drug supplied by a chemist. The danger lies in the disease not being recognised, and as long as those responsible for the sick are content to seek the services of an unqualified authority, we fail to see how the law can protect them against themselves except by making it illegal for any chemist to supply any remedy without the authorisation of a duly qualified practitioner. Questioned as to whether the medicine the man had taken had anything to do with the death, the witness replied that he could not say, but that no medical man would have prescribed such a mixture for a patient suffering from

disease of the heart and kidneys, as was the deceased. The chemist here remarked that the mixture contained a small quantity of chlorodyne and sal volatile. On the coroner calling his attention to the fact that he had offended against the Pharmaceutical Act the following conversation ensued:—

"The Chemist: It is a difficult thing to be a chemist at the present day. All chemists ought to be doctors, it seems to me. You have to say how people are to take their breakfasts, dinners, teas, and suppers, and how to use every half-pennyworth of stuff you sell.—The Coroner: But you know that by prescribing poisons you are committing an illegal act, for which you can be punished, and it is my duty to tell you so. I know your difficulties, and no doubt you think it hard that when a person comes to you late at night you are not allowed to serve him, but I must tell you that you run a great risk if you prescribe poisons.—The Chemist: I do not prescribe for people as a rule, and it is impossible for a chemist to say whether a person is suffering from heart disease.—The Coroner: But chemists must not act in the dark. You know it is beyond the province of a chemist to prescribe poisons.—The Chemist: Then medical men should not do their own dispensing. It seems an anomaly, because the Government allows me to sell as much chlorodyne as I like provided the bottle bears a stamp."

THE PROHIBITIVE PRICE OF ABSOLUTE ALCOHOL.

THERE are few agents at the present time which play a more important or useful rôle in practical scientific operations than absolute alcohol. Indeed, its use is indispensable in the prosecution of chemical, bacteriological, and physiological researches, to say nothing of the necessity of its employment in the preparation of the fluids used in sero-therapeutics. Yet all who are actively concerned in these important lines of research are severely handicapped because of its excessive price, very nearly the whole of which accrues to the Excise. On the Continent the retail price of absolute alcohol is considerably less than that charged in this country, and there is little doubt that this is one of the sources of the increased facilities in research work which obtain there; at any rate, its cost here militates against such progressive work. Surely in the interests of science and progress the authorities could be induced to grant a special concession in this matter to *bona-fide* research workers and to those engaged in unravelling the mysteries of disease. Why should not a memorial be drawn up and signed by influential members of the various scientific societies and presented in the proper quarter? We feel sure that our remarks will appeal to the majority of the members of the scientific professions.

THE DIFFUSION OF SMALL-POX.

THE number of fresh cases of small-pox notified in London last week was 7 and the admissions to the institutions of the Metropolitan Asylums Board 8, against 8, 8, and 6 respectively in the preceding three weeks. The end of the week found 35 patients in hospital, an increase of 3 on the previous Saturday. The disease does not obtain any great hold on the metropolis, nor is it completely shaken off. Mr. Wynter Blyth relates small-pox has been successfully combated under inauspicious circumstances in Marylebone last month. Four virulent cases were removed from premises the ground-floor of which was used as a small general shop. Prompt removal of the patients and closure of the shop under payment made to the tradesman have resulted in staying the disease. This instance is in striking contrast to the case which led to such disaster a few months ago in the same parish. In the provinces the news is generally of a reassuring nature. We are glad to see that despite its two registered deaths Birmingham had only some half-dozen fresh attacks; whilst Liverpool with the same number of deaths registered had only some dozen cases coming newly to light. Lancashire was otherwise fairly free.

from the disease. In Edinburgh, in the third week of January, 7 cases of small-pox were reported and 2 deaths were registered; whilst in Dublin in the same period the admissions to hospital were 61, as compared with 32 71; and 78 in the preceding three weeks, the last number having been erroneously stated in the weekly return as 83 and the corresponding number of patients under treatment having been stated to be 10 in excess of the actual number. Of the 10 deaths registered in Dublin in the week in question 5 were of vaccinated persons—1 an infant nine days of age, and the rest adults—and 4 of unvaccinated adults, the facts as to the remaining fatal case not being known. On the morning of Sunday, Jan. 20th, 310 patients were in hospital (of whom 134 were convalescents at Kilmainham), a fall from 335 a week earlier. The disease seems to be spreading in Ireland, news coming of its presence at Newry, Longford, Drogheda, Geray, and other places.

MEDICAL EVIDENCE AT INQUESTS.

ON Jan. 11th a man shot himself through the head with a revolver in the kitchen of his house in Wigan. He had returned home on that day, after an absence of some months, only half an hour before committing the fatal act. A medical man who was summoned and who arrived probably within thirty minutes of the shot being fired, found that he was already dead and that there were, in fact, signs of rigor mortis of the muscles of the jaw. The only wound was situated two inches behind the right ear and two inches below the parietal eminence. At the inquest, which was held on Jan. 14th, this gentleman was not called on to give evidence. Our ordinary sense of the fitness of things requires that a medical man should be referred to in cases involving injury or death, yet in this instance the coroner took upon himself to have the lesions described by a police constable. The family medical attendant was present and deposed to the deceased having had delirium tremens last year. It is unquestionable that the condition and surroundings of the deceased ought to have been described to the Court by the medical man who noted them shortly after the tragic occurrence.

A LEAD PENCIL IMPACTED IN THE AXILLA MISTAKEN FOR FRACTURE OF THE CLAVICLE

DR. SINCLAIR TONSEY in the *New York Medical Journal* describes the removal of a lead pencil four inches long which had been mistaken for six weeks for a necrotic fragment of the clavicle. The patient came to hospital (Roosevelt) presenting a sinus in the axilla and one below the middle of the clavicle, while a probe introduced into either sinus encountered a hard rough surface suggestive of necrosed bone. He stated that six weeks previously he had fallen and hurt his shoulder very badly, and that he had been attended immediately by two physicians, who said that his collar-bone was broken and applied suitable bandages. In the course of the next four weeks a very large swelling formed below the clavicle and another in the axilla. After examinations at a number of hospitals he was admitted as a ward patient in one of the largest hospitals in New York. There the two abscesses were incised, but it was decided not to attempt to remove the necrotic fragment until a later date. Ten days afterwards he was brought to the Roosevelt Hospital for treatment. Dr. Tonsey found that the hard fragment was freely movable when pushed upon by the probe, and also that pressure in the axilla was transmitted to the hard fragment below the clavicle. It was then perfectly clear that some kind of a spike had been driven into the axilla and had broken off, after penetrating so far that its point could be felt below the middle of the clavicle. The sinus below the clavicle was enlarged and the

lead pencil withdrawn, to the astonishment of the patient and his friends. The entrance of the pencil is easily explained; the boy had climbed a lamp post to light his bicycle lamp, and his feet slipped off the ornamental ledge which passes horizontally around the post about four feet from the ground. As he fell a lead pencil in his waistcoat pocket caught on this ledge and was driven into the axilla and broken off out of sight.

THE LINK SHELL TRUSS.

WE have again to warn our readers that advertisements in respect of this truss are being issued in which, as we said in our notice on Nov. 24th, 1894, our comments have been incorrectly quoted, and additions made thereto not warranted by those comments. We also call attention to the letter of apology from the maker of the truss printed by us on Nov. 24th, 1894. We cannot sufficiently express our indignation at the use made of our comments.

ENGLISH AND AMERICAN LIFE ASSURANCE.

AN interesting paper on Some Points of Difference between Life Assurance Medicine in America and in England was read before the Life Assurance Medical Officers' Association on Wednesday last by Dr. Glover Lyon. The paper was based upon a visit to New York, and brought out in strong contrast the various points wherein the methods of American life assurance offices differ from ours. One of the most striking features of life assurance in America is its colossal size: in the case of some offices nearly 500 medical reports are made every day. Speculation is an element less common in England than in America, and fraudulent attempts to obtain policies on bad lives are also more common in the less limited West. And not only does the material differ, but the method employed regarding the selection of lives widely differs in the two countries. The medical directors in America are usually dependent, or almost entirely dependent, upon their salaries, and they cannot be directors of more than one company. Thus they are at the mercy of the executive for their livelihood, and their opinion is not, as in England, unfettered. Large salaries are offered by American offices to encourage attention to special points in life assurance; but the medical officer has not the same facilities for keeping in touch with his profession as his English brother, who invariably combines with his official duties the labours of a private practice. In America, again, policies are more readily granted than in England, litigation frequently follows, and sometimes ends in the discomfiture of the medical officer who recommended the acceptance of the risk. The gist of Dr. Glover Lyon's interesting paper was to show that on the whole the methods adopted in England compare favourably with those in America; but, as a rebuff to any patriotic "swagger" on our behalf, he urged strongly that something should be done by our medical officers to make the forms in general use in the various offices more uniform.

AT the last preliminary meeting of the University Court of the University of Wales, held at Shrewsbury on Jan. 25th, Lord Aberdare was unanimously elected, subject to the approval of the Crown, the first Chancellor of the University. Dr. Isambard Owen was elected Senior Deputy Chancellor and Mr. A. C. Humphreys-Owen, M.P., Junior Deputy Chancellor.

DR. JOHN FRASER, Deputy Commissioner in Lunacy for Scotland, has been appointed a Commissioner in the room of Sir Arthur Mitchell, K.C.B., whose retirement we recently notified; and Dr. John Francis Sutherland, medical officer to Glasgow prison, has been appointed Deputy Commissioner in the room of Dr. John Fraser.

THE next meeting, on Tuesday, Feb. 5th, of the Pathological Society of London will be devoted to a discussion upon Pneumococci, with relation especially to Immunity. Dr. Washbourn will open the discussion; Dr. A. E. Wright will contribute some notes on the bacteriology and pathological chemistry of pneumonia; and several members have already promised to take part in the debate. A series of microscopical slides of the various appearances of pneumococci, under different conditions, will be shown.

THE degree of Doctor of Medicine in the University of Oxford was conferred on Tuesday last, by decree of Convocation, upon Professor J. S. Burdon Sanderson, F.R.S., Regius Professor of Medicine in the University of Oxford. On the same day Dr. T. Clifford Allbutt, F.R.S., Professor of Medicine in the University of Cambridge, was elected a member of the General Board of Studies in that University.

THE Duke of Cambridge will preside at the Biennial Festival of the National Hospital for the Paralysed and Epileptic, Queen-square, to take place at the Hôtel Métropole, on April 2nd.

WE may again remind our readers that the Hunterian Oration at the Royal College of Surgeons of England will be delivered on Feb. 14th, at the College, by the President, Mr. J. W. Hulke, F.R.S.

THE library of the Royal College of Surgeons of England will be closed on Feb. 13th, 14th, and 15th on account of the Hunterian Festival.

NEXT Friday evening, Feb. 8th, an address will be delivered at the Royal Institution by Dr. G. Sims Woodhead on the Antitoxin Serum Treatment of Diphtheria.

THE Royal Commission on the opium question began its final sittings on Wednesday, Jan. 23rd.

BRITISH INSTITUTE OF PREVENTIVE MEDICINE.

THE REPORT OF THE DIRECTOR.

DURING the last three months the preparation of horses for the "antitoxic" serum has been proceeded with. Twenty-one horses are now under treatment, and all of them, three excepted, are now ready for bleeding. Their serum is of such strength that 0.0001 c.c. mixed with a quantity of toxine fatal to a guinea pig in twenty-four hours will prevent the occurrence of any symptoms. Dr. Bertram Hunt has now taken charge of the diphtheria cultures and the preparation of the serum, and the laboratory at the Institute's farm is now ready and in working order. The greatest difficulty we have had to contend with was the obtaining of an absolutely aseptic serum. During the necessary manipulations it is almost impossible not to expose the serum for a short time to unfiltered air. In order to avoid all risks a special room is now being fitted up at the farm, which will be specially devoted to all the necessary manipulations. Experiments on the concentration of the curative substance in the serum have been in progress. Mr. Nolan and I have been able to concentrate the serum to perfect dryness without its losing any of its properties. The dried serum can then be re-dissolved in a very small quantity of

distilled and sterilised water. We are also at work on the isolation of the curative substance.

The Metropolitan Asylums Board have been using the serum in the hospitals under their control. The results have been satisfactory.

Thus Dr. Matthews, medical superintendent of the Fountain Hospital, Grove-road, Lower Tooting, S.W., writes:—

"1. Cases of diphtheria admitted during October and November, 1894, not treated by antitoxin: Number of cases, 123; number of deaths 33; mortality per cent., 30.8.

"2. Cases treated during December-January with antitoxin: Number of cases, 61; number of deaths, 10; mortality per cent., 16.3.

"In these 61 cases all clinically diphtheria, diphtheria bacilli were found in 55; the 10 deaths occurred out of this number, giving therefore a death-rate of 18.1 per cent. in cases where bacteriological confirmation was present. But for the purpose of comparison the clinical and not the bacteriological diagnosis must be taken, inasmuch as the latter method was not used in the first group of 123 cases. The mortality amongst the cases treated with antitoxin shows a very striking reduction and has produced a strong impression in its favour upon my mind. Its ultimate value has doubtless yet to be fixed, but I feel no doubt that in it we possess an agent of great value in the treatment of diphtheria. With regard to after-effects, rashes with pyrexia were observed in some cases, but no serious or lasting ill-effects. The patients to whom the treatment was applied, were almost exclusively children of ten years and under. But this limitation would not have been made had our supply of antitoxin been sufficient for patients of all ages. In thanking you for your great courtesy in supplying me with material, I beg to express my sense of the services rendered to the cause of suffering humanity in this country by the enterprise of the British Institute of Preventive Medicine."

Dr. MacCombie, medical superintendent of the South-Eastern Fever Hospital, Hatfield-street, New Cross, S.E., states that

"Since November last, when he first began to treat diphtheria cases by antitoxin serum, 102 cases of diphtheria have been admitted and 51 have died; calculated on admissions and deaths, the mortality amounts to 14.7 per cent. From Jan. 1st, 1894, to Nov. 26th, 1894, his average diphtheria mortality was 25.6 per cent. It varied in different months, the highest being 38 per cent., and the lowest 23.0 per cent. in August. Dr. MacCombie does not feel justified in expressing an opinion as to the value of the treatment, but he is favourably impressed with its apparently beneficial action in cases in which the treatment begins before the fourth day of illness. He also draws attention to the unpleasant effects which, in his opinion, sometimes accompany the use of the remedy."

Dr. Gayton, medical superintendent of the North-Western Fever Hospital, Haverstock-hill, N.W.,

"Has treated 43 cases in which the presence of the diphtheria bacillus had been demonstrated; 2 died—mortality 4.6 per cent. Of these cases 1 was under one year of age, 22 were from one to five years old, 11 were from five to ten years old, and 9 were ten years old or upwards."

Dr. Caiger, the medical superintendent of the South-Western Fever Hospital, Stockwell, S.W., writes as follows:

"Owing to the facilities which you have been good enough to provide, I have been enabled to treat all severe cases of diphtheria admitted into this hospital with antitoxin for the past two months. I am pleased to be able to state my conviction that its use has been attended with most satisfactory results—results which my experience justifies me in asserting could not have been expected with previous methods of treatment. Not only does the reduction in mortality imply the saving of a considerable number of lives, but the treatment, if commenced at a sufficiently early date, is successful in warding off the necessity for tracheotomy, and thus, by averting suffocation, effects a reduction of the pain and terrors of a most distressing disease; while the painlessness of the treatment and the absence of any serious after-effects is to my mind as striking as the success of the remedy itself. Although, to ensure a favourable result in grave attacks of the disease, it is of the first importance that the patient should be brought under treatment at an early date, if possible not later than the third day, in a certain number of cases the most marked benefit has followed when the inoculations have not been commenced until two or three days later. It is my intention, when the number of serum-treated cases has become somewhat larger, to bring the results obtained at this hospital before the medical profession, and I desire to express my indebtedness to the Council for affording me the opportunity of using the serum at such an early date."

Mr. Bruce, medical superintendent of the Western Fever Hospital, Fulham, S.W., writes:—

"The number of cases treated with antitoxin at this hospital is comparatively small on which to base a conclusion as to the efficacy of the remedy. The results, judged from a clinical standpoint, have, however, so far been extremely favourable—sufficiently so, I think, to justify me in expressing a very high opinion of the value of the remedy in the treatment of diphtheria. The statistical evidence furnished herewith points to a like conclusion:—

¹ Too much importance is not to be attached to these statistics, as Dr. Gayton informs me that out of these 43 cases, 7 only were really severe.—M. A. K.

The Cases of Diphtheria treated at the Western Fever Hospital with Antitoxin.²

TABLE I. (A).—From Nov. 26th, 1894, to Jan. 25th, 1895.

Age Periods.	Admissions.	Deaths.	Type of Disease.			Complications.	
			Severe.	Moderate.	Mild.	Rashes.	Arthritis.
0 to 5 years	40	5	15	18	7	10	1

TABLE II.—Case Mortality from Diphtheria at the Western Fever Hospital.

Year.	Admissions.	Deaths.	Percentage of Mortality.
1891	141	54	38·3
1892	247	78	31·5
1893	256	94	36·7
1894 (to Nov. 26th)	507	176	34·7
Total	1151	402	Average = 34·9.

TABLE III.—Admissions &c. from Nov. 26th, 1893, to Jan. 25th, 1894, being the corresponding period of last year when no antitoxin was employed.

Age Periods.	Admissions.	Deaths.	Percentage.
0 to 5 years	20	12	60
5 to 10 years	21	6	28·57
10 to 15 years	7	—	—
And upwards	10	1	10
Total	58	19	32·85

Ten of these cases were complicated by laryngitis, with six deaths. Tracheotomy was performed in five cases, with one recovery, and intubation in one case, which was fatal.

It will be seen from these reports that, whereas during the time that the antitoxin treatment was being used at Homerton the mortality in the other hospitals of the Metropolitan Asylums Board remained practically the same, the mortality in all these hospitals at once fell when the antitoxin treatment was begun in them. Dr. Gayton's mortality of 4·6 per cent. in 43 cases of diphtheria in which the diagnosis had been established by bacteriological examination is, as far as I know, the lowest mortality on record.

M. ARMAND RUFFER, Director.

ABSTRACT OF REPORT OF BACTERIOLOGICAL DEPARTMENT BY DR. ALLAN MACFADYEN.

During the past year there were twenty-five workers in the laboratories. Amongst the students were medical men from Russia, Africa, India, Australia, New Zealand, and Canada.

² In all these cases the diagnosis was confirmed by bacteriological examination. Four are still in a critical condition.

The numbers have increased this year, there being at the present moment twenty students at work. An evening-class in bacteriology has been started and is well attended. The increase in work has necessitated the appointment of an assistant bacteriologist. Dr. R. T. Hewlett has already entered on the duties of the post.

A gratifying feature is the increase in the number of those engaged in original investigations. In 1894 six researches were commenced and completed. At present five gentlemen are engaged upon various investigations under the supervision of Dr. Macfadyen.

Dr. Hewlett is continuing the preparation of the tetanus antitoxin and is assisting Dr. Macfadyen in his investigations.

Dr. Macfadyen has, with the assistance of Dr. Hewlett, prepared mallein and tuberculin. These substances will be immediately tested upon animals, and there will soon be an adequate supply for the use of members of the veterinary profession.

The preparation of the toxines of erysipelas has also been undertaken. When ready the action of these toxines will be tested in cases of sarcoma.

An inquiry is being made for the county council of Derbyshire with regard to a supposed outbreak of hydrophobia.

Mr. Barnard has undertaken to give instruction in microphotography to the students in the laboratory, and it is believed that this will prove a valuable addition to the teaching resources.

ADDENDUM.

The following arrangements have been made with regard to the sale of the curative serum for diphtheria and tetanus and the bacteriological examination of cases of diphtheria or suspected diphtheria.

1. The serum may be obtained by any registered medical practitioner on application to the Director of the Institute, 101, Great Russell-street, London, W.C., or to Messrs. Allen and Hanburys, Plough-court, Lombard-street, London, E.C.

2. The price of the serum is fixed for the present at 1s. 6d. for 30 c.c., but it is to be distinctly understood that the serum is for the use of the United Kingdom and Colonies only. Under no circumstances whatever is it to be sent to other countries.

3. In order to facilitate the bacteriological examination of suspected case of diphtheria, a special sterilised box for the transmission of membrane will be sent to any medical man on receipt of one shilling in stamps. The fee for examination of the membrane will be 2s. 6d. Several cases having occurred in which apparently virulent bacilli have been found in patients who were to all appearances perfectly recovered from an attack of diphtheria, whenever the bacillus has been isolated, the examination will be repeated every fortnight without extra charge until the patient has been found to be free from diphtheria bacilli.

4. The institute possess a horse immunised against tetanus and are ready to supply a certain amount of tetanus antitoxin. The price of this will be 2s. 6d. for 1 gramme of dried serum, or 2s. for 10 c.c. of liquid serum. The supply is limited to the United Kingdom and the colonies, and none is to be sent to foreign countries under any circumstances whatever.

SMALL-POX IN DERBYSHIRE IN 1893.

DR. SIDNEY BARWISE, the medical officer of Derbyshire, has in his report on the county for 1893 brought out with admirable clearness the relations which small-pox bore in the county during that year to the vaccinated and unvaccinated communities which were invaded by the disease. As many as 1049 cases came to the knowledge of the local health officers in the administrative county, with ninety-three deaths, the disease having been largely spread by the agency of navvies working on the Dore and Chinley railway. Overcrowding prevailed, and the men wore each other's "overalls" while working, added to which they worked in night and day shifts after sleeping in the same beds. But what was even worse was the deplorable absence of hospital accommodation, temporary erections being in some instances prepared with all practicable speed, though, after all was done, only one-half of the total cases were isolated. And it was not for the want of money, since Dr. Barwise computes as a low figure the expenditure of £10,000 on the 1000 attacks in one and another way, such as loss of wages, isolation provision, and

the like. But, as he remarks, one cannot tell where the cost of an epidemic will end, the poor-rates often being saddled for years with the relief of the dependants of sufferers. Chesterfield with its ninety-six cases might have been freed from more than 80 per cent. of them had hospital accommodation been in actual readiness for the first cases. Other districts suffering heavy invasion were Newbold and Dunston, 178 cases; Chesterfield rural, 178 cases; and Ecclesall Bierlow rural, 222 cases. On the matter of influence of vaccination on the outbreak, Dr. Barwise is able to give data of his own as regards Whittington with its 135 cases and thirteen deaths down to March, 1894. Of 159 vaccinated persons in infected dwellings, aged under ten years, 6.9 per cent. were attacked and none died; of twenty-one unvaccinated in the same case and of similar ages, 71.4 were attacked and 23.8 per cent. died. In the two classes in the same order at ages over ten years the attack-rates were 35 and 100 per cent.; whilst the death-rates were 2.3 and 25 per cent. of the 300 and the four persons exposed to infection. True, the figures on which the results are based are small, but the rates are very startling, showing in an unmistakable manner the great need for vaccination, and equally for revaccination, looking to the almost complete immunity from attack of children once vaccinated and the complete immunity of those attacked from fatal illness. In the whole administrative county the deaths from small-pox were 8.9 per cent. of cases, and of 499 attacks concerning which the facts are known as to vaccination the per case mortality was 8.6 per cent., made up of 3.9 in the vaccinated and of 25 in the unvaccinated. Another point of interest is that 40 per cent. of the small-pox deaths were in children under five years of age, a figure which would seem to be taking us back to the early years of the century, when it was 90 per cent. of the total small-pox deaths. We must go back to a quinquennial period prior to the seventies for such a rate in England. The Derbyshire rate on children under five years of age in 1893 was twice that of England five years previously. Dr. Barwise sees in these data the result of the terrible laxity growing up over the county—and we may say country—in the matter of enforcement of the vaccination laws, and the figures certainly afford food for reflection on the part of professional agitators and of our legislators. We also commend them to the notice of the Vaccination Commission. Space does not enable us to dwell further on the point here, or to quote the interesting cases of malignancy of infection and of the protecting influence of vaccination to which Dr. Barwise refers. Such a report as this makes us wish that the printed reports of health officers were commonly available for the reading public, as by purchase or in other ways.

OYSTERS AND TYPHOID FEVER.

MUCH has appeared and is appearing in the daily press upon the subject of the possible communication of disease as a result of the consumption of oysters in a raw state. The President of the Local Government Board has instituted an inquiry into the circumstances under which the cultivation and storage of the bivalvular mollusc and other shell-fish around the coast are carried out as the result of a report from Dr. Thorne Thorne, the medical officer of the Board. The following is the report of a bacteriological investigation of water from an oyster bed and of oysters from the same source, made by Professor Crookshank, M.B., Director of the Bacteriological Laboratory, King's College, London:—

"This investigation was made at the request of Dr. Fuller of New Shoreham. The first sample of water, despatched by Dr. Fuller on Dec. 17th, consisted of sea water with a thick deposit of mud at the bottom of the vessel. The water and the deposit were separately examined. Experiments were made by special methods for detecting the presence of the bacillus of typhoid fever. The results were negative. Further experiments were made in order to isolate other bacteria present in the water and in the deposit, and to examine their exact nature. The colonies which developed in plate-cultivations were very numerous, and it was necessary to obtain a fresh sample of water and to repeat the experiments in order to obtain complete isolation of the individual colonies and to establish pure-cultivations of each species. The results obtained with the second sample will be referred to directly. There was no septic

odour in the plate-cultivations obtained from the first sample of water. The muddy sediment was examined by similar methods. There were no typhoid fever bacilli present, and the micro-organisms which were isolated and examined, both microscopically and in pure-cultures, were found to be well-known harmless bacteria. The majority of these colonies were the result of the multiplication of a harmless liquefying bacterium. On Dec. 20th three oysters were despatched by Dr. Fuller. The liquid of the oyster was mixed with liquefied gelatine and several plate-cultivations made. The number of colonies which developed was surprisingly small. The colonies were found to represent only five different species of bacteria. All of these were studied in the form of pure-cultivations, and were easily recognised as familiar and harmless species. The marked difference in the number of bacteria in the liquid of the oyster and in the water of the oyster bed suggests an interesting line of inquiry. The second sample of water, despatched on Jan. 11th, was so treated that the individual colonies would be completely separated even if the bacteria were found to be present in very considerable numbers. Nine separate experiments were made, and the average number of colonies which developed amounted to 50,000 in a cubic centimetre. The colonies consisted very largely of a non-liquefying and a liquefying bacterium. Other species were similarly isolated and studied in their microscopical and biological characters, and all were recognised as well known and harmless bacteria. There was no septic odour from the cultivations, and, in fact, the complete absence of foul-smelling or saprogenic bacteria was very striking; and in none of these experiments was the typhoid fever bacillus present. The number of bacteria, however, calls for some comment. The colonies were far in excess of those found in pure sea water, and a similar number, if found in drinking water, would raise a suspicion of sewage contamination unless a very considerable interval had elapsed between the time of taking the sample and its subsequent examination. The question therefore arises whether the excessive number of colonies in this particular sample of sea water indicates sewage contamination or is due to a want of cleanliness in the oyster bed and the presence of organic matter from other causes than sewage. The absence of septic and foul-smelling micro-organisms points to absence of sewage, unless sea water has a special action upon those micro-organisms which we expect to find wherever there is unquestionably mixture with sewage. The question of the presence or absence of such contamination can, however, be ascertained by further investigation and by local inquiry. The question which I have been asked is whether oysters from this particular bed are likely to be injurious to the consumer. From the bacteriological investigation of the samples of water and of oysters submitted for examination I am of opinion that there is no evidence, from the bacteriological examination, which would lead me to condemn the oysters as dangerous or unfit for food. I am led to this conclusion by the absence of typhoid fever bacilli and by the absence of any septic micro-organisms, and by the fact that all the micro-organisms which I succeeded in isolating were perfectly harmless species. I would venture to add, however, that more than a bacteriological investigation is required to relieve public anxiety upon the question of a possible danger arising from the consumption of uncooked oysters. The possibility of a constant or intermittent contamination of the oyster beds by sewage ought to be carefully inquired into. Any local evidence which justifies a suspicion of typhoid fever resulting from the consumption of oysters from a particular oyster bed ought to be carefully followed up. I am of opinion that the danger of the contamination of oysters with the specific cause of typhoid fever has been exaggerated, but I am equally convinced that it is quite possible that just as unboiled milk mixed with typhoid-infected water may distribute typhoid fever among the consumers, so also the liquid of uncooked oysters may be the means of conveying typhoid fever if water infected with typhoid fever is imprisoned between the valves of the oyster. The oyster may thus be the means of mechanically transferring typhoid bacilli to the mouth of the consumer, and the question then arises whether the bacillus has been derived from the sewage-fed oyster bed or from typhoid-infected water in the establishments in which the oysters are retailed. Here there is need for further and careful inquiry. Have there been groups of cases of typhoid fever traced to oysters distributed from some,

particular oyster bed, or have the cases been traced to any particular establishment or retail shop, so that suspicion may rest equally upon the water at the place of distribution to the consumer and upon the water of the oyster bed? I do not believe that either the cow or the oyster can elaborate typhoid fever from sewage, but it is quite possible that oysters may mechanically convey typhoid fever, just as milk mixed with infected water may be the medium for distributing this disease. In both cases it is more than probable that the danger is much exaggerated."

DINNER TO DR. JAMESON, C.B.

It was a happy thought which impelled some of the fellow-students of Dr. Leander Starr Jameson at University College to arrange for a dinner to him at which he would meet those amongst whom he worked in college and hospital, where for two years he held the position of resident medical officer. The dinner took place at the Whitehall Rooms on Thursday, Jan. 24th, and passed off with great *éclat*. The chair was occupied by Mr. Christopher Heath, senior surgeon to University College Hospital, having on his right the guest of the evening. Upwards of 120 sat down, many having come from long distances to be present on the occasion. Amongst those present were Sir J. Russell Reynolds, F.R.S., Sir J. E. Erichsen, F.R.S., Sir John Williams, Dr. Bastian, F.R.S., Dr. Gowers, F.R.S., Dr. F. T. Roberts, Dr. Poore, Mr. Tweedy, Mr. Bilton Pollard, Mr. S. J. Hutchinson, Dr. Bradford, F.R.S., Dr. Sidney Martin, Dr. Radcliffe Crocker, Dr. Corfield, Mr. Meredith, Mr. Quarry Silcock, Mr. A. J. Pepper, Dr. Dawson Williams, Dr. Sidney Coupland, Mr. Pearce Gould, Mr. Stanley Boyd, Mr. Buckston Browne, Dr. Campbell Pope, Dr. B. H. Allen (Hastings), Dr. Colgate (Eastbourne), and Mr. Farrell (Eastbourne). After the toast of the Queen had been duly honoured the Chairman in a brief speech proposed the health of Dr. Jameson, which was enthusiastically received.

Dr. JAMESON: Mr. Chairman and Gentlemen.—I thank you most heartily for this more than kind reception to-night. I need not say how gratifying it is to me that any work of mine should be considered worthy of such recognition from you, many of whom have been intimately associated with me during my early career. I need not say how honoured I feel at the presence here to-night, on my right hand and on my left, of those professors and teachers who, in my time as a student, more than twenty years ago, were even then the leading men at University College, then, and I believe still, one of the leading schools of medicine in the kingdom. It is a special gratification to me to have the honour of the presence of two of my old teachers who have been lately recognised by the Queen as leaders of the profession by special distinction of title. Gentlemen, it is more than seven years ago since I practically left the profession. I assure you it has often been to me, for many reasons, a regret that I have done so, and I shall always continue to feel a sense of regret. Yet it seems to me that I have rather drifted out of it than that I have deliberately left it. During the first year of the new work to which I turned I sometimes thought of going back to medical practice, but I soon found that the profession had also drifted away from me. Indeed, I began to wonder whether, in the first instance, it had not drifted away from me rather than I from it. I soon saw, from the rapid manner in which medical science was advancing, that if I attempted to resume it I should have to go to school again to become competent to treat patients. I felt that I should not have energy enough for that. Hence, by a natural consequence, as my work increased and my sphere became larger and of greater importance, my own interest in it increased also. So my old profession and I got further apart. I have gradually drifted from the medical man into the administrator, and yet, perhaps, after all it is more correct to say that the one has become merged into the other. I have always recognised that any capability I may have shown for my present work has been due in great measure to the experience I gained in the several resident posts I held in University College Hospital, and especially to the influence of the last two years, when in the time of some of the professors here to-night I held the much-coveted post of Resident Medical Officer. In those two years I learnt what I consider are the main

elements of success for anyone who attempts to govern or to administer. They are these two principles—first, never to promise anything you cannot undertake; secondly, to believe that one's own opinion is not the only opinion in the world, but that other people are worth listening to, and other opinions are worth considering. If these two principles are recognised in action, if they are thoroughly acted up to, I believe it will be found to be good for those who govern, good for the man who governs, and good for those to whom the administrator is responsible. I have thus to thank University College and University College Hospital for the groundwork of any success I may have had in my different sphere of work. I have also to thank University College Hospital for the memory of what I may truly say were the best years of my life. I remember the days when I secured a dressership under Mr. Erichsen, and only two days ago I met in the train my former house surgeon, Mr. Backston Browne. I wish, gentlemen, that I could go through those days again. Later on I was fortunate enough to secure the post of house physician in the hospital to Dr. Russell Reynolds, and still later a house surgeoncy to Mr. Marshall, when I had the supreme pleasure of beating my friend, Mr. Pepper. I can assure you that when I obtained this post I felt more gratification and was more proud of myself than I was last year when I arrived at Bulawayo. Although I had gone through a considerable amount of disagreeable work, and although the anxiety which preceded the success was very great, I think the examination for that house surgeoncy, and especially the horrible *viva-voce* part of it, gave me more anxiety than I experienced in all that campaign. Now, gentlemen, I will not trouble you with a digest of the downfall of Bulawayo or even of an outline of our Company's proceedings; but our Chairman mentioned the subject of what he was kind enough to call the "libel" on myself during our operations. If you will allow me, I should like to say a few words for myself on that subject. Our Chairman also said that this was not a political meeting; I hope sincerely that it is not. But when a friend of mine—one of our secretaries—this evening told me that you intended to give me a dinner, I felt that I did wish one thing. Whatever the country may think of the methods of our procedure in Matabeleland, I am anxious that the members of the profession to which I have the honour to belong should understand the origin of what took place. I myself, previous to our troubles last year, always hoped that the Matabele question would be settled without having recourse to force. I knew that Lobengula had always said he would never fight with the "white men," and I believed that he had absolute control over his Indunas. I, therefore, believed that we should come through all our difficulties without any conflict. I was egotistical enough to think that had I been at Pretoria when the trouble began I should have been able to stave off any conflict; but I was 200 miles away, and I will give you as short an account as I can of what happened. When I arrived I found on both sides of the road the Matabeles carrying off their goods in preparation for a fight; but a year before the same thing had happened, and I then took up a firm position and settled matters. I thought I might do the same thing again. It turned out that I was wrong. Only two things were possible—either 2000 people, including every white man, would have lost their all, and there would have been such a butchery of Mashonas as had never been heard of before, or we must use force—we must go to Bulawayo. When the war was over, after the settlement, I went over the whole of the facts, and heard the same account from everyone. I found I was right in regard to the king—he never wanted to fight; but I was wrong with regard to the natives. They had entirely the upper hand of the king. There were only two people who did not want to fight—one was the king, the other was one of the Indunas who had been over here. I wish you to know to-night that we adopted the only possible method we could adopt. We were driven into the campaign, and during the three preceding years we had done everything we possibly could to avoid such a thing as a conflict. No one could be more ready than I am to condemn any attempt to bring on a war with these unfortunate races. I have troubled you enough. I can only thank you most heartily for the extremely kind welcome you have given me.

Dr. Jameson concluded by proposing the health of the Chairman, which was most cordially received.

The toast of the Secretaries, Dr. Radcliffe Crocker and Mr. Quarry Silcock, to whom the success of the gathering was

largely owing, was also received with heartiness, and the proceedings, which had been enlivened by songs and recitations by Dr. Roberts, Dr. Campbell Pope, and other visitors, came to a close. It was generally agreed that a more pleasant reunion had seldom been held, an opinion enhanced by the fact that in the case of many of those present twenty years had elapsed since they were fellow-students together.

THE REGISTRAR-GENERAL'S ANNUAL REPORT FOR 1893.

THE Registrar-General for England and Wales has just issued his fifty-sixth annual report, dealing with the vital statistics for the year 1893. The marriages in the year were equal to 14.7 persons married to 1000 persons estimated to be living in the middle of the year; this rate showed a further decline from the rates in recent years, and was lower than the rate in any year since 1888, when it was 14.4. This decline in the marriage-rate was coincident with a further decline in the ratio of British exports to the population. The birth-rate was equal to 30.8 per 1000, which, although showing a fractional increase upon the rate in 1893, was 1.1 per 1000 below the mean rate in the ten years 1883-92. The proportion of births born out of wedlock, which has shown a fairly steady decline in a long series of years, was equal to 4.2 per cent. in 1893, and corresponded with the proportion in each of the two preceding years.

The meteorological conditions of 1893 were very exceptional. The mean temperature of the air was considerably above the average, the mean for each month from February to October inclusive showing an excess which was relatively largest in March, April, May, and August. The rainfall was only 20.1 in., and was 4.2 in. below the average, the greatest deficiency occurring in the four months ending with June. Thus the mean degree of humidity of the air was exceptionally low, lower indeed than in any previous year since 1852. These meteorological conditions exercised an undoubtedly unfavourable effect upon the mortality returns for the year.

The 569,958 deaths recorded in England and Wales during 1893 were equal to a rate of 19.2 per 1000 persons living. This rate showed a very slight increase upon the rate in 1892, and was identical with the mean annual rate in the ten years 1883-92. It ranged from 14.7 in Westmorland and 15.0 in Berkshire, Buckinghamshire, and Dorsetshire to 20.5 in Durham, 20.7 in Staffordshire and in the East Riding of Yorkshire, 20.8 in London, and 22.4 in Lancashire. The excess in the death-rate was mainly confined to children and young adults, while the rates among persons past middle age, on the other hand, showed a considerable decline. Infant mortality, measured by the proportion of deaths under one year of age to registered births, was equal to 159 per 1000, and exceeded the rate in any year since 1870; this excess was in great measure due to the exceptional fatality of diarrhoea. It is noteworthy that the increase of mortality in 1893 was entirely confined to town districts. The urban rate rose from 19.5 in 1892 to 20.2 per 1000, whereas the rural rate declined from 18.1 to 17.4.

The main feature of the increased mortality was the excess of deaths due to zymotic or specific febrile diseases, to which 94,126 deaths in 1893 were referred, equal to a rate of 3.2 per 1000, exceeding the rate in any of the ten preceding years, which showed a mean rate of 2.6. The mortality directly or indirectly referred to influenza showed a further considerable decline in 1893, and the death-rates from measles, scarlet fever, and whooping-cough were below the average, whereas the deaths referred to diarrhoea and diphtheria showed a large excess, and those from small-pox and enteric fever a very considerable increase. The increase in the death-rate from enteric fever was probably due in great measure to the high temperature and deficient rainfall, which undoubtedly caused the exceptional mortality from infantile diarrhoea. The death-rate from diphtheria was equal to 318 per million living, and was higher than in any previous year on record since 1859; the mean rate from this disease in the ten years 1883-92 did not exceed 175 per million. The greatest fatality from this disease occurred in the south-eastern counties, the rate in London and in nine almost contiguous counties averaging 612 per million living. The rates from measles and whooping-cough were exceptionally low. The diarrhoeal death-rate was 999 per million living, against

an average rate of 653 in the ten years 1883-92; the rate in 1893 has only been exceeded four times during the past twenty years. Small-pox mortality, which had been remarkably quiescent during the three years 1889-91, increased in 1892. The fatal cases of this disease were 451 in 1892, and further rose to 1457 in 1893. The deaths from puerperal fever and from the accidents of childbirth were exceptionally numerous, and the rate from these causes were higher than in any year since 1876. The proportion of deaths referred to premature birth and congenital defects, to registered births, also showed a further increase upon that recorded in recent years. No fewer than 20,076 deaths in the year were referred to different forms of violence, the rate from this class of causes somewhat exceeding the average.

Such are the main features of the detailed returns for England and Wales in 1893, the unfavourable nature of the figures being mainly due to the long drought and to the high temperature during the spring and summer. It is at any rate satisfactory to know that the increased death-rate in 1893 has been more than counterbalanced by the unprecedentedly low rate in 1894, which was only 16.6 per 1000.

CORK SOCIETIES' MEDICAL OFFICERS' INDEMNITY FUND.

THE following subscriptions to this fund have been received by Mr. Denis Dempsey Donovan, hon. treasurer, 51, King-street, Cork:—

N. J. Hobart, M.D. (Cork)	£20 0 0	D. J. O'Mahony, M.D. (Cork)	£5 0 0
Professor E. R. Townsend, M.D. (Cork)	20 0 0	P. T. O'Sullivan, M.D. (Cork)	5 0 0
P. J. Cremen, M.D. (Cork)	20 0 0	P. Tracey, M.D. (Cork)	5 0 0
Professor S. O'Sullivan, M.D., F.R.C.S.I. (Cork)	20 0 0	N. H. Runciman, M.D. (Cork)	5 0 0
D. D. Donovan, M.D. (Cork)	20 0 0	M. J. Murphy, M.D. (Cork)	5 0 0
Professor H. Corby, M.D. (Cork)	20 0 0	R. Dalton, M.D. (Cork)	5 0 0
T. Gelston Atkins, M.D. (Cork)	20 0 0	M. O'Connell, M.D. (Cork)	5 0 0
J. Cotter, M.D. (Cork)	20 0 0	P. J. Daly, M.D. (Cork)	5 0 0
Professor C. Yelverton Pearson, M.D. (Cork)	20 0 0	D. Flynn, M.D. (Cork)	5 0 0
H. R. Townsend, M.D. (Cork)	20 0 0	H. Hobart, M.D. (Cork)	5 0 0
W. A. Cummins, M.D. (Cork)	20 0 0	N. J. Townsend, M.D. (Cork)	5 0 0
E. Magner, M.D. (Cork)	20 0 0	E. Murphy, M.D. (Cork)	5 0 0
J. Giusani, M.D. (Cork)	15 0 0	C. Roche, M.D. (Cork)	5 0 0
Philip Lee, M.D. (Cork)	10 0 0	E. W. Allsom, M.D. (Cork)	5 0 0
T. B. Moriarty, M.D. (Cork)	10 0 0	T. Callaghan, M.D. (Cork)	2 2 0
P. J. Hayes, M.D. (Cork)	10 0 0	M. Cahill, M.D. (Cork)	1 0 0
J. MacMahon, M.D. (Cork)	10 0 0	P. Dee, M.D. (Cork)	1 0 0
P. Oscar Woods, M.D. (Cork)	10 0 0	J. O'Meara, M.D. (Cork)	1 1 0
D. C. O'Connor, M.D. (Cork)	5 0 0	H. T. Butlin, F.R.C.S. Eng. (London)	5 0 0
		W. P. Herringham, M.D. (London)	1 1 0
		A. Hargreave, M.D. (Tralee)	1 1 0

It will be perceived by the communication from one of our special correspondents in Ireland that the fund has received considerable augmentation since this list was sent to us.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6849 births and 3797 deaths were registered during the week ending Jan. 26th. The annual rate of mortality in these towns, which had increased in the preceding four weeks from 18.0 to 21.7 per 1000, declined again last week to 18.7. In London the rate was 17.6 per 1000, while it averaged 19.5 in the thirty-two provincial towns. The lowest rates in these towns were 11.3 in Leicester, 13.5 in Brighton, 14.6 in West Ham, 14.7 in Bradford, and 15.0 in Croydon; the highest rates were 22.0 in Burnley, 23.1 in Manchester, 23.7 in Wolverhampton, 24.1 in Preston, and 28.0 in Liverpool. The 3797 deaths included 328 which were referred to the principal zymotic diseases, against 363 and 338 in the preceding two weeks; of these, 75 resulted from measles, 69 from whooping-cough, 56 from diphtheria, 47 from "fever" (principally enteric), 42 from diarrhoea, 35 from scarlet fever, and 4

from small-pox. No fatal case of any of these diseases occurred last week in Leicester; in the other towns they caused the lowest death-rates in Nottingham, Derby, Burnley, and Huddersfield, and the highest rates in Sheffield, Gateshead, Preston, Sunderland, and Wolverhampton. The greatest mortality from measles occurred in Portsmouth, Sheffield, Newcastle-upon-Tyne, and Gateshead; from scarlet fever in Wolverhampton; from whooping-cough in Plymouth, Wolverhampton, Oldham, Halifax, Sunderland, and Gateshead, and from "fever" in Halifax. The 56 deaths from diphtheria included 29 in London, 6 in Birmingham, and 3 in Manchester. Two fatal cases of small-pox were registered in Manchester and 2 in Liverpool, but not one in London or any other of the thirty-three large towns. There were 35 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 26th ult., against 23, 28, and 33 at the end of the preceding three weeks; 8 new cases were admitted during the week, against 8 and 6 in the preceding two weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital, which had been 1779, 1718, and 1653 at the end of the preceding three weeks, was 1662 on Saturday last; 186 new cases were admitted during the week, against 126, 130, and 154 in the preceding three weeks. The deaths referred to diseases of the respiratory organs in London, which had increased from 319 to 399 in the preceding three weeks, declined again to 324 last week, and were 310 below the corrected average. The causes of 79, or 2.1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Cardiff, Bradford, Sunderland, Newcastle-upon-Tyne, and in eight other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Leicester, Salford, and Blackburn.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the preceding three weeks from 21.8 to 28.3 per 1000, declined again to 24.2 during the week ending Jan. 26th, but was 5.5 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 19.2 in Leith and 19.4 in Aberdeen to 26.0 in Greenock and 27.3 in Glasgow. The 698 deaths in these towns included 42 which were referred to measles, 18 to whooping-cough, 11 to diarrhoea, 9 to scarlet fever, 5 to diphtheria, 5 to "fever," and 2 to small-pox. In all, 92 deaths resulted from these principal zymotic diseases, against 113 and 100 in the preceding two weeks. These 92 deaths were equal to an annual rate of 3.2 per 1000, which exceeded by 1.6 per 1000 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 58 and 45 in the preceding two weeks, further declined to 42 last week, of which 25 occurred in Glasgow, 10 in Edinburgh, and 7 in Aberdeen. The 18 deaths referred to whooping-cough were within one of the number in the preceding week, and included 13 in Glasgow. The fatal cases of scarlet fever, which had been 6 and 12 in the preceding two weeks, declined to 9 last week, and included 5 in Glasgow and 3 in Edinburgh. The deaths referred to diphtheria, which had been 14 and 9 in the preceding two weeks, further fell to 5 last week, of which 2 occurred in Glasgow and 2 in Edinburgh. Of the 5 fatal cases of "fever," 4 were recorded in Glasgow; and of the 2 deaths from small-pox, one occurred in Leith and one in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 215 and 235 in the preceding two weeks, declined to 186 last week, but exceeded by 53 the number in the corresponding period of last year. The causes of 57, or more than 8 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased from 25.4 to 40.9 per 1000 in the preceding four weeks, declined again to 31.0 during the week ending Jan. 26th. During the past four weeks of the current quarter the death-rate in the city has averaged 32.8 per 1000, against 18.6 in London and 23.9 in Edinburgh. The 208 deaths registered in Dublin during the

week under notice showed a decline of 66 from the number in the previous week, and included 20 which were referred to the principal zymotic diseases, against numbers increasing from 10 to 23 in the preceding three weeks; of these, 7 resulted from small-pox, 5 from "fever" (principally enteric), 3 from diarrhoea, 2 from scarlet fever, 2 from whooping-cough, 1 from diphtheria, and not one from measles. These 20 deaths were equal to an annual rate of 3.0 per 1000, the zymotic death-rate during the same period being 1.3 in London and 3.4 in Edinburgh. The fatal cases of small-pox, which had been 11 and 10 in the preceding two weeks, further declined to 7 last week. The deaths referred to different forms of "fever," which had increased from 2 to 4 in the preceding three weeks, further rose to 5 last week. The mortality from whooping-cough and from diarrhoea showed a decline from that recorded in the preceding week, while that from scarlet fever showed an increase. The 208 deaths in Dublin last week included 30 of infants under one year of age and 72 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from the exceptionally high numbers in the preceding week. Three inquest cases and 4 deaths from violence were registered; and 72, or more than a third, of the deaths occurred in public institutions. The causes of 20, or nearly 10 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-CAPTAIN R. H. MOORE, A.M.S., has been ordered to join at Netley for duty about the 8th proximo. Leave from Netley has been granted to Surgeon-Captain Reid from Feb. 1st to March 24th, and to Surgeon-Major Whitehead from Feb. 4th to March 5th. Surgeon-Major F. J. Jencken, M.B., has been ordered to proceed to Netley, for duty, on the 1st proximo. Surgeon-Major O'Brien and Surgeon-Captains Macleod and Wilson have embarked in the *Dilwara* for India. Surgeon-Majors Webb, Wilkinson, and Ryan, and Surgeon-Captain Clark have arrived from India in the *Britannia*.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Lieutenant-Colonel Richard Gillham Thomsett, A.M.S., has been posted to the Medical Charge of the Station Hospital, Mandalay; and Surgeon-Major William Amherst Daniel Cowen, A.M.S., has been posted to the Medical Charge of the Station Hospital at Poonamallee. The services of Surgeon-Captain Charles Duer, M.B., I.M.S. (Bengal), are replaced at the disposal of the Military Department. Brigade-Surgeon-Lieutenant-Colonel William Roe Hooper, Civil Surgeon and Superintendent of the Lunatic Asylum, Lucknow, retires from the service.

NAVAL MEDICAL SERVICES.

Fleet-Surgeon Robert Hall More, M.D., has been placed on the Retired List, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets.

The following appointments are notified:—Staff-Surgeons: John J. Dinns to the *Undaunted*, and R. E. Biddulph to the *Inflexible*.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant Peter M. Kerr, M.B., having resigned his Volunteer medical appointment, ceases to be an officer of the Army Medical Reserve of Officers. Surgeon-Captain Thomas McCraith Foley, 1st East Riding of Yorkshire Volunteer Artillery, to be Surgeon-Captain.

VOLUNTEER CORPS.

Rifle: 1st Volunteer Battalion, the Prince of Wales's Own (West Yorkshire Regiment): Surgeon-Major A. O. Wiley resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the Battalion on his retirement. 1st Volunteer Battalion, the Royal Sussex Regiment: Surgeon-Captain D. W. Giffard resigns his commission.

VOLUNTEER MEDICAL STAFF CORPS.

The London Companies: Herbert William George Macleod, M.B., to be Surgeon-Lieutenant.

THE WAR BETWEEN CHINA AND JAPAN.

In an article on "The War between China and Japan"

in the February issue of the *United Service Magazine*, Colonel Maurice sounds a note of warning to British residents who are still lingering in Chinese towns for fear of running the gauntlet of the disorderly soldiery marauding in the country. With half a million of men round Pekin, whose habits are filthy and who have hardly any knowledge of the meaning of the words discipline or organisation, with an absence of the faintest notion of the most ordinary military or sanitary precautions, there is every probability that a pestilence in some form or other will follow upon the melting in the spring of the snow, which has been defouled by vast numbers of men and animals. "Even as regards the march of the Japanese, in the early spring, on Pekin, I think," says the writer, "it will require all their admirable organisation, discipline, and sanitary skill to prevent the contagion reaching their army. A medical question of the greatest general interest needs to be answered. Within what time after warm, moist weather sets in ought we to expect actual illness to follow upon the hopeless sanitary neglect of vast disorderly congregations of men with many neglected animals? I think that the medical papers would do us an excellent service if they would answer it."

THE LATE CHOLERA OUTBREAK IN THE EAST LANCASHIRE REGIMENT.

It will be remembered that a very severe outbreak of cholera occurred in the East Lancashire Regiment at Lucknow last year. A committee, presided over by Surgeon-Lieutenant-Colonel Hutcheson, Sanitary Commissioner in the North-West Provinces, has recently been inquiring into the cause of the outbreak in question, and it is alleged that the propagation of the disease has been traced to have taken place through the instrumentality of the barrack-room filter. The sand used as a filtering medium had been taken from a *ghat* on the Gamti in the immediate vicinity of a native quarter where cholera had prevailed during the last hot weather. The filtering medium proved to have been the source and vehicle of the cholera infection. When the first company affected moved into camp their filter was, it is said, passed on to other companies and gave rise to the disease in them. The issue of the report of the committee, giving a detailed history of the evidence and results of their investigation, will, it is needless to say, be awaited with interest.

THE PAY OF PRINCIPAL MEDICAL OFFICERS OF ARMY CORPS IN INDIA.

The *Broad Arrow* calls attention to the fact that the pay of the surgeon-major-generals who may be appointed Principal Medical Officers of the Army Corps in India under the new organisation will be 2000 rupees a month, which will mulct the officers of the Army Medical Staff of 500 rupees per mensem. The present rate of pay in Bombay and Madras for the Principal Medical Officers of the Army Medical Staff is 2500 rupees. The secretary to the Principal Medical Officer will get 150 rupees extra if an officer of the British service, and if of the Indian Medical Service 600 rupees a month consolidated pay. For some time past it has been known that the Army Medical Staff officers lent by the Secretary of State for War to the Indian Government would suffer pecuniarily by the new arrangements.

EXPERIMENTAL RESEARCH IN INDIA.

A deputation from the Indian Medical Congress waited upon Sir Anthony MacDonnell, controlling the Home Department, to urge upon the Government of India the extension of facilities for the study of preventive medicine and the prosecution of scientific research in that country and also to protest against the Cantonment Act Amendment Bill. Sir Anthony MacDonnell in his reply assured the deputation of his interest in the objects in view and announced that, in addition to the bacteriological laboratory at Agra, a similar institution for experimental research was to be established at Lahore. The third clause—which was the one principally objected to in the Cantonment Act Amendment Bill—has, we are glad to say, since been withdrawn.

THE LATE COLONEL SANDWICH, C.B.

A good many medical officers who have served in Egypt and the Sudan will have read the news of the recent death, after a very brief illness, of Colonel Sandwich, C.B., the newly appointed administrator of Dominica, with great regret. Colonel Sandwich served for a long time in Egypt on the headquarter staff at Cairo, and was deservedly popular and much respected; he was a typical soldier in

manner and bearing, and affable and courteous to all with whom he came in contact. The late officer was the brother of Dr. F. M. Sandwith of Cairo.

THE HEALTH OF THE TROOPS DURING THE LATE CAVALRY MANŒUVRES.

The Inspector-General of Cavalry, in his report of Dec. 1st last on the cavalry division lately assembled under his command in Berkshire, says the health of all ranks was very good. The rations are described by the medical officer as of excellent quality. The six bell tents used for hospital purposes proved more than sufficient. All the sick were sent to Aldershot; the railway company arranged to provide at short notice a through carriage for serious cases. No accident of any importance occurred during the drills and manœuvres.

A NEW WATER SUPPLY FOR SOLON.

The troops quartered at the small hill station of Solon, known to most medical officers who have served in the Punjab, have of late years suffered more or less from typhoid fever, which was thought to be attributable to the water-supply. A sum of money has been granted by the Indian Government for its projected improvement.

DEATHS IN THE SERVICES.

Deputy-Surgeon-General C. J. J. Jackson, of the Bengal Medical Service (retired), at Nice, on Jan. 16th, aged sixty-four. Brigade-Surgeon John Charles Wishaw, Bengal Army (retired), on Jan. 20th, at Mentone, aged sixty-two.

The *Pioneer Mail* states that Surgeon-Colonel Cleghorn, Inspector-General of Civil Hospitals in the Punjab, has been offered the post of Surgeon-General with the Government of India, in succession to Surgeon-General Rice.

The sixty-ninth session of the Army Medical School, Netley, terminated on Thursday, Jan. 31st, when the prizes were distributed by Mr. W. H. Russell, LL.D.

The *Malabar* sailed from Bombay on the 18th ult. with ten invalids for Netley.

The hired transport *Britannia* arrived on the 25th ult. with fourteen invalids for Netley Hospital.

Correspondence.

"Audi alteram partem."

"THE GENERAL MEDICAL COUNCIL AND THE OBSTETRICAL SOCIETY."

To the Editors of THE LANCET.

SIRS,—Dr. Playfair does but scanty justice to those of our profession who object to the State recognition of midwives. Without entering fully into the matter, it may be pointed out that no objection has been raised to the Obstetrical Society or any other society examining midwives, but exception has been taken to the practice of issuing a pretentious paper to successful examinees which is capable of being and has been known to be used as a certificate allowing the holder to practise midwifery. If the council of the Obstetrical Society would agree to the suggestion made that it should print in red letters across the certificate "This certificate does not entitle the holder to practise either surgery, medicine or midwifery" everyone would be satisfied. Perhaps I may be allowed to correct the statement that there is a desire to attempt to abolish midwives altogether; the desire is to prevent the introduction of the foreign system of the practice of midwifery by State licensed midwives. Dr. Playfair will not prevent the success of the opposition by representing it as being small; it is much stronger than he imagines, and certainly his evidence before the Select Committee of the House of Commons does not add anything material in favour of legislation. It is not very easy to understand why the General Medical Council should mete out treatment to the Obstetrical Society different to that which it administers to the gentlemen who employ unqualified assistants. The one has encouraged unlicensed practice by issuing a colourable imitation of a professional certificate; [the others employ the unlicensed, who no doubt are often more competent than those possessed of the society's certificate. Perhaps I may be permitted to remind Sir John

Williams that any ill-feeling that exists is the result of the attempt on the part of those who are attached as teachers to medical schools and lying-in institutions, to thrust down the throat of the profession an unpalatable bolus. His letter will do more to make the profession believe that those who are attached to schools as teachers possess interests which are not identical with those of the rest of the profession.

I am, Sirs, your obedient servant,
Hatfield, Jan. 27th, 1895. LOVELL DRAGE.

To the Editors of THE LANCET.

SIRS,—Every year I issue a more important looking parchment to students who have achieved honourable mention in my class, which might just as well be called a colourable imitation of a diploma," is a clause in Dr. Playfair's letter in THE LANCET of Jan. 26th in his defence of the Obstetrical Society of London for the very proper objection raised by the General Medical Council against that Society as a diploma-granting body. Is it not a fact that all lecturers upon obstetrics in our medical schools award similar "certificates" to those students who have distinguished themselves in that particular branch of the curriculum? Dr. Playfair's contention, therefore, is somewhat irrelevant, inasmuch that the successful students in obstetrics are entitled to those respective certificates—although they go for nothing; whereas the "certificates," or, rather, "diplomas" (which are most misleading to the general public, who usually look upon their holders as being legally qualified women), granted by the Obstetrical Society afford them a right to practise midwifery and to sign death certificates for still and premature births, &c., alike, which, I maintain, is fraught with very grave objection. What is easier than for one of those so-called midwives to certify for a premature birth or otherwise in cases where an illegal operation may have been performed by some unscrupulous person outside, unknown to the particular midwife engaged?

If we are to accept the Obstetrical Society's diplomas to women for the future to practise a branch of the medical profession, why should not men likewise be admitted to their examination?

I am, Sirs, yours faithfully,
J. FRENCH BLAKE.
High-street, Putney, S.W., Jan. 26th, 1895.

"ISOLATION OF CASES OF OVARIOTOMY."

To the Editors of THE LANCET.

SIRS,—Dr. Cullingworth and I have stated our views on this subject, and I am quite willing to leave the matter to the judgment of the profession; but I should like to be allowed to draw attention to the fact that Dr. Cullingworth concedes the point that isolation is useful, after ovariectomy, "for exceptionally serious cases and cases that seem to be taking a markedly unfavourable course," whilst he makes no attempt to controvert my contention that it is impossible to select these cases with certainty before operation. Hence, if every patient is to have the best chance of recovery, every patient should have the advantage of isolation until convalescence is assured. It seems to me that there is a great danger that the very marked success which follows ovariectomy as a rule may have a tendency to jeopardise, in many ways, the more serious cases. A simple ovariectomy is not a difficult operation, but the diagnosis is never quite certain and the simplest looking case may tax the resources of the surgeon and the vital powers of the patient to the uttermost. I hope I may be permitted to add a cordial acknowledgment of the very kind way in which Dr. Cullingworth has referred to my work in his letter to you, and in the recent debate at the Royal Medical and Chirurgical Society. Such recognition and the manner of expressing it are most gratifying to me, and it is a special satisfaction to think that Dr. Cullingworth and I differ on the isolation question with mutual esteem and goodwill.

I am, Sirs, your obedient servant,
Portman-street, Jan. 26th, 1895. JOHN D. MALCOLM

THE MEDICAL ENTRIES AT THE UNIVERSITY OF EDINBURGH.

To the Editors of THE LANCET.

SIRS,—My attention has been called to an annotation in your issue of Jan. 26th, headed "The Medical Schools," in

which it is stated that "the new entries at the Edinburgh University show a total of 136, the number of students on the roll, including the fifth year and upwards, being 1213." I beg to inform you that these two numbers should be 207 and 1248 respectively. Hoping that you will be good enough to make this correction.

I am, Sirs, yours faithfully,
Edinburgh. J. KIRKPATRICK,
Secretary of Senatus.

* * We give publicity to this letter of correction from the Secretary of Senatus of the University of Edinburgh with pleasure. The figures as supplied to us from the University of Edinburgh in answer to an application were as follows:—Number of new students, 136. Students attending the University—first year, 199; second year, 244; third year, 222; fourth year, 241; fifth year and upwards, 307; total, 1213. The return was dated Nov. 15th, 1894, a date which we considered would nearly correspond with the date at which the returns were collected from the London schools. The return would thus be most useful for comparison with our table. The difference in the figures shows the accession to the roll of Edinburgh students that has taken place since the beginning of the current medical year.—ED. L.

THE DENTIST'S EDUCATION.

To the Editors of THE LANCET.

SIRS,—Very considerable alterations should be made in the curriculum of the L.D.S. Eng., not only in the interests of the dental student, but in those of the greater profession to which the specialty is gradually becoming more closely allied. The first step should be to make a third year of hospital study compulsory. At the present time a dental student need only pass two years at hospital, and although he must be signed up for three years' dental mechanics the third year of this course is usually ignored, and in many cases the apprenticeship is merely nominal. Consequently, many students have to crowd the whole of their education into two hospital years, and even if they get through the examination they are neither likely to prove a credit to their profession nor an unmixed blessing to the community. There is no earthly reason why students should not be compelled to pass a practical examination in dental mechanics before they enter hospital, and this would prevent the possibility of two or three of the best years of a young man's life being wasted or would throw the onus of his failure on those who accepted the premium for his apprenticeship. Two years of hospital are not sufficient, for in that brief time the hapless dental student has not only to dissect and to attend the lectures and demonstrations required for the second examination of the Conjoint Board, but has also to fulfil an elaborate special curriculum. He must attend lectures on dental surgery (two courses), dental anatomy (two courses), dental mechanics, and dental metallurgy, and every student ought to spend several hours a day between 9 A.M. and 4.30 P.M. in attending patients. He must do hundreds of "fillings," some of which will take at least three hours each, must learn to extract teeth, must make and fit dentures, regulation plates, and "crowns," and must, in general terms, acquire manipulative skill of the highest order. Dental students should be considered much cleverer than medical students if they are expected to do all this properly in two years.

The examination for the L.D.S. Eng. is grievously comprehensive and varied, commencing with written papers on anatomy, physiology, surgery, dental anatomy (human and comparative), and dental surgery. Every candidate has a practical examination of about six hours' duration on dental mechanics and practical dental surgery. At the *visa-voce* he is examined at four tables in succession—viz., anatomy, surgery, dental anatomy, and dental surgery. Nothing but severe cramming can get the candidates ready, and it is the rule, not the exception, to cram for the L.D.S. Eng. No astonishment need be felt at the high percentage of rejections. There is small gain in jumbling together anatomy, physiology, surgery, metallurgy, microscopy, materia medica, dental anatomy, dental surgery, and operative dental surgery in one final test at the end of two years. The examination should be divided into two parts. The first should be held at the end of the second year, embracing all the

above-named subjects excepting surgery, dental surgery, and practical dental surgery, and these three subjects should form the final examination at the end of the third year. Glasgow is far ahead of England in having divided the subjects of the L.D.S. into two parts. I believe that the need of a third year is widely felt amongst dental teachers, and that the extension would not materially check the registration of new students, whilst the value of the L.D.S. diploma would be enhanced and the status of the dentist would be improved. The adoption of a fifth year in the medical curriculum must be followed by a third year in the dental curriculum, or the hospital training of the dentist will become shorter still by comparison with that of the medical practitioner. The medical profession would like to feel that every dental surgeon had passed at least the second examination of the Conjoint Board, but unless the dental course is to be extended there is little hope of improvement.

I am, Sirs, yours faithfully,

F. NEWLAND-PEDLEY, F.R.C.S. Eng.

Devonshire-place, W., Jan. 25th, 1895.

"THE DEBATE ON THE NATURE AND TREATMENT OF PERITONITIS AT THE OBSTETRICAL SOCIETY."

To the Editors of THE LANCET.

SIRS,—I think it a waste of time to discuss whether micro-organisms cause peritonitis. If Mr. Tait is not convinced by the evidence before the profession he is not likely to be convinced by anything. I am glad to have given him the opportunity of better defining his opinions as to the benefit of purgatives after abdominal operations. Some years ago he said he cured peritonitis with them, as Mr. Malcolm has shown in his letter to you published in your last week's issue. Then he denied this. I supposed that he meant that he prevented it. Now we know that he claims neither to prevent nor cure peritonitis with purgatives, but simply to relieve intestinal distension. In this, I think, the profession will have no difficulty in agreeing with him.

I am, Sirs, yours faithfully,

Jan. 29th, 1895.

G. ERNEST HERMAN.

To the Editors of THE LANCET.

SIRS,—Mr. John D. Malcolm has made this subject so peculiarly his own that it is dangerous for any other dog to bark at it. Nevertheless, at the famous debate at the Harvelan Society he ingenuously admitted that his powers of oratory were not such as to permit him to make his meaning clear. I do not think his literary efforts are a success of a higher order, otherwise I certainly have spoken in vain. I offer to let him have his own way, in spite of all tradition and former belief that the cases I described are not peritonitis. I agree to admit his conclusion that the cases that die are peritonitis, because we make post-mortems of them and find it so. We do not make post-mortems of those that we help to recover by purging, and therefore I cannot say that they are cases of peritonitis. Mr. Malcolm says they are not cases of peritonitis, and I gracefully yield to the authority; but I say they would be cases of peritonitis if they were left alone or had opium, and therefore I say that we beat the peritonitis. Even this may be wrong, and therefore I say that I do not care for "pathologico-metaphysical conundra." Surely, after this concession Mr. Malcolm will either leave me alone or go and get trepanned.

I am, Sirs, yours truly,

Birmingham, Jan. 26th, 1895.

LAWSON TAIT.

THE LONDON MEDICAL STUDENTS AND THE UNIVERSITY OF LONDON: A GRIEVANCE.

To the Editors of THE LANCET.

SIRS,—The London medical students have a real grievance. The London University medical degree is too hard for the majority of students. Some recognise this from the first, and do not attempt to get it; others give up trying only after repeated failures. In Scotland the case is different. A man of ordinary ability and fair industry is sure to get a medical degree; in London this is not the case. At the end of their period of study, and after they have had a clinical experience

which it would be impossible to get in Scotland, many London students who have worked hard have to start in practice without a medical degree or to take one elsewhere. Some who have a year or two to spare go to Durham, and not a few to Brussels. It is sometimes assumed by graduates of other universities that there must be something wrong about a man who goes to Belgium for a degree. This assumption is unfair and often groundless. Many able, experienced, and learned men have found it the only method by which they could take a medical degree for which their previous training had fully entitled them. The fact that the degree of the University of London is much more difficult to get than that of the Scottish Universities is a real hardship to the London medical student, because his inability to get a degree may place him at an unfair disadvantage in practice if he have as a competitor a man who, although he has had less experience, is still a "Dr." whilst he is a "Mr." Your readers will, I think, agree with me that there are few country towns which could not furnish examples to the point.

I am, Sirs, your obedient servant,

York-street, W., Jan. 24th, 1895.

RICHARD SISLEY.

. Dr. Sisley enumerates with precision points which we have frequently taken occasion to bring to our readers' notice. We are happy, however, to print his letter, as a *résumé* of the position of the London medical student is well-timed at the present moment.—ED. L.

"THE ABSENCE OF SUGAR FROM NORMAL URINE PROVED BY A NEW AND SIMPLE METHOD."

To the Editors of THE LANCET.

SIRS,—A careful perusal of Sir George Johnson's interesting article in THE LANCET of Jan. 12th and an extensive experience of the picric acid test and most other of the reactions which have been proposed from time to time for the detection of diabetic sugar in urine induce me to make some comments on the facts and arguments adduced by Sir George Johnson.

No one will dispute that the test described by Sir George Johnson, and so strongly advocated by him, is one of great simplicity and facility of application; but perhaps all will not so readily endorse his claim that for clinical and life assurance purposes no method of testing for glycosuria equals this for ease, rapidity, and absolute trustworthiness. In the first place, Sir George Johnson does not appear to claim that the reaction is absolutely reliable in its application to urine containing less than two grains of sugar per ounce, if, indeed, it is trustworthy at all in the case of this and smaller proportions. A fluid ounce of water weighs 437.5 gr., not 480 gr., as I gather from Sir George Johnson's closing paragraph he supposes to be the case. Hence the so-called "percentage"—or, more correctly, the number of grains per 100 fluid grains—can be found by dividing the grains per fluid ounce by 4.375. Therefore two grains per ounce correspond to 0.46 "per cent." It would be absurd for me to question the view apparently held by Sir George Johnson that any proportion of sugar materially less than this may be safely neglected; but it is a proposition that many of those who suffer from glycosuria in its milder forms will be delighted to believe. It seems probable, also, that such cases will receive a warmer welcome from the insurance companies than has been the case in the past. Further, Sir George Johnson holds that a trace of sugar in normal urine, if existent, is of no practical importance to the physician. On all such points I at once bow to Sir George Johnson's opinion, but when he approaches the question from a chemist's standpoint I may say frankly that I am not convinced either by his arguments or his experimental evidence.

Sir George Johnson bases the whole of his argument on the assumption, in my opinion quite unwarranted, that it is possible to recognise slight differences of tint in liquids which are each of them somewhat strongly coloured. Thus, the kreatinine present in normal urine admittedly produces a blood-red colour with the picric acid test, and it is only the production of a red-brown colour (exactly imitated by a solution of acetate of iron) over and above this blood-red tint that we are desired to observe

Yet even this unavoidable colour produced by normal urine is apt to be more than twice as intense in one sample as in another, the coloration ranging, according to Sir George Johnson, from a tint represented by 0.5 gr. per ounce in some urines to 1.2 gr. in others; yet the allowance made for this variable interference is a constant one. In Sheffield, we are accustomed to estimate the percentage of carbon in steel by dissolving a weighed portion of the sample in nitric acid and comparing the depth of brownish tint possessed by the solution with that given by a standard steel treated similarly. Many hundreds of samples are tested annually in my laboratory by this process, which bears a close resemblance to the estimation of diabetic sugar by Sir George Johnson's micro-saccharometer. But our wide experience with this process has taught us that it is quite impossible to form an accurate opinion on the depth of tint of solutions so intensely coloured as those employed by Sir George Johnson. Hence his quantitative results must be of the roughest kind, and, while amply sufficient to form a judgment as to the progress made by a diabetic patient, are quite inconclusive as evidence on the vexed question of the presence of traces of sugar in normal urine. Sir George Johnson himself finds that the picric acid test gives no indication of sugar in solutions containing less than 0.01 per cent., and leaves it to be inferred that in solutions more concentrated than this the colour is produced with an intensity exactly proportionate to the amount of glucose present. This, on the face of it, is extremely improbable, and it is far more likely that the reaction becomes gradually more imperfect as the dilution increases, so that in highly dilute solutions considerably more sugar is required to produce a given tint than in concentrated solutions. The same argument applies to the colour produced by kreatinine. The fact is that, with the picric acid test, we are dealing with a variety of coloured liquids ranging in tint from pale yellow to deep coffee-brown, and their variability renders any exact quantitative inferences wholly impossible. First we have the colour of the urine itself, varying through a considerable range. Then Sir George Johnson must have been exceptionally fortunate if he has succeeded in obtaining picric acid which does not give more or less reddish coloration when boiled with caustic alkali. I have a specimen now before me which gives a colour indistinguishable except in depth from that yielded by a sample of normal urine; and on diluting with two measures of water the liquid resulting from the application of the picric acid test to the latter the tints are identical. Repeated recrystallisation has failed to prevent this behaviour entirely, and it follows that the purification of the reagent is difficult, and the unpurified acid untrustworthy. Then the caustic potash is apt to contain traces of cyanides which react with picric acid exactly like sugar. Next there is the colour (varying from 0.5 to 1.2 grs. per oz.) produced by normal urine; and finally we have the colour due to actual sugar. Yet, with all these variable conditions and sources of error, Sir George Johnson wishes us to regard an observation of the depth of colour produced with picric acid as conclusive evidence of the absence of traces of sugar from normal urine. It may be absent, but Sir George Johnson has not proved it. On the other hand, we have the production by numerous observers of the definite crystalline glucosazone by the treatment of normal urine with phenyl-hydrazine, a reaction far more convincing to chemists than the non-production of a red-brown coloration in presence of a blood-red, which is substantially the negative evidence on which Sir George Johnson's position rests.

In one of his communications to THE LANCET Sir George Johnson pooh-poohs the indications of the phenyl-hydrazine test because it detects traces of sugar undiscoverable by picric acid; but he has made no attempt to show what substance it is which, from its resemblance to glucose, has repeatedly deceived the very elect. He has also to explain away the fact (or traverse the method) that Dr. Pavy has, by operating on very large quantities of normal urine, isolated a substance which not only responds to the phenyl-hydrazine test, but reduces solutions of bismuth and copper, and last, but not least, ferments on addition of yeast.¹

Returning to the application of picric acid to the examination of urine for comparatively large quantities of sugar, it is evidently desirable to avoid, if possible, a test which gives more or less reaction even with normal urine. It is also an advantage to employ a test which consists in the discharge of a colour, as in Pavy's modification of the

copper test, rather than one in which colour is produced. Even Sir George Johnson would probably give the preference to a test of this sort, unaffected by kreatinine or uric acid, if it were as rapid and easily applied as that with picric acid. The above desideratum is met by a test proposed by M. Crismer,² based on the decolorisation of the red coal-tar colour known as "safranin" when heated in alkaline solution with glucose. I have myself proved that the reagent is not affected by kreatinine or uric acid, and M. Crismer states that it is also indifferent to kreatine, chloral, chloroform, hydrogen peroxide, &c., and is only slowly reduced by solutions of albumen. Hence, any notable discharge of colour produced by a sample of urine previously freed from albumen may confidently be set down to the presence of sugar. In carrying out the test I employ equal measures (1 drachm each) of the sample of urine, normal soda or potash (liquor potassæ, B.P.), water, and a solution of one part of commercial safranin in 1000 of water. The mixture, which has a deep red colour, is heated in a test-tube until it boils freely, agitation and consequent contact with air being avoided as much as possible. If the urine contain more than 0.1 per cent. of sugar the liquid will be decolorised, but otherwise the red colour will remain intact or be only partially discharged. If the colour be destroyed, the test may be repeated with two or three times the volume of safranin solution that is used of urine, every additional measure of safranin solution which is found to be decolorised representing roughly 0.1 per cent. of sugar in the sample. If more than four or five measures are required there is marked glycosuria, and it is desirable to dilute a portion of the urine to ten times its bulk with water, and make a fresh experiment with equal measures of this diluted urine, potash, and safranin solution.

The end of the reaction is indicated by the liquid becoming pale yellow and turbid. The colouring matter is not actually destroyed, but merely reduced to a leuco-derivative, which rapidly becomes red again on exposure to air.

In my experience the safranin test is one of the simplest and most certain clinical tests for urinary sugar, and deserves to come into general use. Its advantages over the picric acid test are obvious, while its application is quite as simple. The rough quantitative indications obtainable in the manner above indicated will often afford great assistance to the medical practitioner. On the other hand, attempts to base on the reaction an accurate quantitative method by operating in the manner of Pavy have been unsuccessful.

By employing the safranin in the form of pellets instead of in solution the addition of a definite quantity of the colouring matter would be much facilitated, and the clinical application of the test rendered extremely simple. The alkali might be employed with advantage in the same form, and I am in hopes that this suggestion will shortly assume a practical shape.—I am, Sirs, yours truly,

ALFRED H. ALLEN, F.I.C., F.C.S.,

Vice-President of the Society of Public Analysts.

Surrey-street, Sheffield, Jan. 19th, 1895.

P.S.—Jan. 30th.—The foregoing letter was written before the appearance of Sir George Johnson's letter published in THE LANCET of Jan. 26th. Although it is true that the carbohydrates are by no means the only bodies which react with phenyl-hydrazine to form crystalline compounds, still, if the compound obtained have the same melting point as the osazone yielded by glucose and exhibit the exact crystalline form of glucosazone, it is strong *prima-facie* evidence that we are really dealing with that body. It would be interesting to learn from Dr. Pavy whether he has made any attempt to regenerate the glucose from the crystals of pseudo-glucosazone which he obtained by the application of his process to normal urine; but, even in the absence of this crucial test, the affirmative evidence he furnishes is, to my mind, of incomparably greater weight than the negative reaction with picric acid.

MEDICAL BULLETINS.

To the Editors of THE LANCET.

SIRS,—Now that the sadness of Lord Randolph Churchill's illness has ended in his death, may I call attention to the daily bulletins issued by the physicians in charge of the case? The subject is one that demands the earnest consideration of the medical profession. The system of recording

¹ Physiology of the Carbohydrates, p. 180.

² Pharmaceutische Zeitung, xxxiii., 65; Pharmaceutical Journal, [3], xix., 348.

almost daily the various symptoms occurring may possibly from a clinical aspect be of some interest to the medical world, and their publication in a professional journal might not be very objectionable, though certainly unnecessary. But the severest comment upon them has been made by men of all shades of thought, who could not but wonder at the want of taste and professional reticence exhibited in the record we have daily read in the lay press. From a very early stage of the case the fact was admitted that recovery was hopeless; and yet, in spite of this, the physicians almost daily issued bulletins depicting the varying phases of the case, the gradual sapping of the fortress of life, in a manner that was as regrettable as it was inconsistent with the standard of professional reserve. The world knew that a great life was passing away, but it did not need to know the painful steps leading to the end, and it is impossible to say what good purpose is served by their publication. Personal friends might satisfy their anxiety in the usual way; more than this was inexpedient. Is it possible to hope that in future like cases a wiser reticence, a more discreet caution, may be observed?—I am, Sirs, yours truly,

Jan. 26th, 1895.

E. F.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Hospital Sunday.

NOTWITHSTANDING the very inclement weather which prevailed here on Sunday, Jan. 13th, and the very depressed state of trade and commerce, the collections made, augmented by donations from those who were unable to be present and by some collections made on Jan. 20th, will compare very favourably with those of past years. Up to the present the treasurer has been advised of the sum of £5341. Among other collections are the munificent ones of £797 from the Unitarian Chapel, Renshaw-street; £626 from the Sefton-park Presbyterian Church; and sums of £158, £137, £125, £116, and two of £100 each.

Death from Anthrax at St. Helens.

An inquest was held on Jan. 21st by the county coroner on the body of a man forty-four years of age, who had worked as a labourer for some years for a firm who kept manure works. He went to work on the 16th in his usual health but seemed unwell at dinner time, and his wife noticed a swelling in his neck. He complained of a fluttering sensation there, and that night the swelling had increased. On the following day he was worse and saw Dr. Casey, who sent him to the hospital in a cab. He was there seen by Mr. F. Knowles, who found him suffering from acute inflammation in the neck, with much swelling and great difficulty in breathing. The deceased said he had had a pimple on his neck and had scratched it. He subsequently died from anthrax, and the jury, in returning a verdict of "Death from blood poisoning," suggested that there should be special rules for the guidance of men at similar works.

Fatality at the Liverpool Workhouse.

An adjourned inquest was held on Jan. 17th by the city coroner upon the bodies of three men who had died in consequence of injuries received from a boiler explosion at the Liverpool workhouse. It appeared from the evidence that the deceased men were respectively the engineer, fireman and attendant at the workhouse. The boiler was used for heating the main building and the hospitals. The explosion probably arose from some obstruction in the tank into which steam was periodically blown off and in which the body of a cat was found when it was emptied after the explosion. The engineer died the next day from shock and exhaustion, he having been very severely scalded about the arms and back. The fireman was severely scalded about the scalp, head and eyes, being rendered blind; he had also scalds on the chest and back and a scalp wound, he having been blown across the room. The attendant was scalded very severely about the arms and back. In returning a verdict of "Accidental death" the jury made some suggestions for the prevention of such accidents in future, which the vestry clerk promised should be fully considered.

Neglecting to Notify a Case of Small-pox.

A married woman was brought before the stipendiary magistrate for neglecting to notify to the medical officer of health a case of small-pox which occurred at her residence. A

sanitary inspector called at her house the previous Thursday, and she told him that there was no sick person in the house. On the Saturday he called again, and found her son in bed, his body covered with the eruption of small-pox. The patient had been working at the Birkenhead Docks the previous day and night. He was seen by Dr. Walker, who ordered his removal to the small-pox hospital. A penalty of 40s. and costs was imposed.

The Liverpool Northern Hospital.

The annual meeting of the supporters of the Northern Hospital was held on Jan. 16th, at the town-hall, the Lord Mayor (Mr. W. H. Watts) presiding. In their annual report the committee gratefully acknowledged the receipt of £1498 from the Hospital Sunday and Saturday Fund, expressing the conviction that but for this assistance it would have been impossible to carry on the work of the charity. The horse ambulance had been called out 956 times during the year, and had proved itself to be an invaluable adjunct to the institution. The committee regretted that the negotiations with regard to the new hospital were not yet quite completed, but they were so far advanced that there was now no reason to doubt that, through the munificence of the David Lewis trustees, and with the assistance of the corporation of Liverpool, a most complete and convenient hospital would very shortly be provided. In moving the adoption of the report and accounts the Lord Mayor said that the Northern Hospital was an institution which appealed very strongly to every heart that felt commiseration for human suffering. He had had the pleasure that day of going over the hospital, and had seen the noble work which was being done there, and which was carried on under circumstances of the greatest difficulty. He had been through the various wards, and had seen such an amount of suffering that it made one's heart bleed, and yet the loving care that was being bestowed on each individual case was one of the most satisfactory features that one could estimate. The demands on the hospital had outgrown the accommodation, and the arrangements were very defective and insanitary. He was struck with the crowded state of the wards, and though all that could possibly be done was done they were severely handicapped.

The Proposed New Hospital.

It is greatly to be desired that the new hospital shall not only have ample accommodation for the number of patients for which it must provide, but may also be constructed with a view to future contingencies. The situation of the hospital is now central rather than northern, and there is every probability, owing to circumstances, that a considerable addition to the present number of beds (155) will be required. The matter is to be discussed at the next meeting of the city council on Feb. 6th, and it is to be hoped that a spirit of foresight as well as of generosity will animate all who have to decide this very important matter. The hospital was established sixty-one years ago, and is the second hospital in this city.

Jan. 29th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Queen Victoria's Jubilee Institute for Nurses, Edinburgh.

THE sixth annual report of the Scottish branch of this institute has been published. During the year twenty-three probationers who had received hospital training had been received into the home for district training, and twenty-four had completed their training. At the end of their year the Scottish council was responsible for thirty-three nurses. During the year twenty-one nurses had, on the completion of their training, been engaged by local committees. Eight new local associations had been formed, all being affiliated to the institute. In Edinburgh and Leith, the report says, 2849 cases had been attended. In spite of the benevolent and Christian character of this work the finances of the institute are very unsatisfactory, for, while the ordinary expenditure has been £2046, the receipts have only amounted to £1583, leaving thus a deficit of from £400 to £500, which has been met out of a reserve fund, which, however, is almost exhausted.

The Longmore Hospital for Incurables, Edinburgh.

The cry from this hospital also is for funds. Last year the

accommodation was increased by the building of a new wing, and the hospital can now accommodate 104 patients. It is always full and there are always more applicants than can possibly be admitted. To build and furnish and endow the extension a sum of £15,000 was required and the authorities are still £5000 short of that amount.

Edinburgh University Endowment Association.

Financial assistance is greatly needed by this association also. Last year less money was received than during the preceding year. Amongst other objects to which it refers, the report says: "Another direction in which it would appear that the association is fitted to render substantial assistance is in providing travelling and research scholarships. Many able students are at present hindered by lack of means from undertaking medical or scientific research within the University, which thus loses the benefit of their work. With the aid of research scholarships they would be encouraged and enabled to prosecute such studies, which would be a direct advantage to the University both from the increased number of students who might be attracted to Edinburgh by such scholarships and from the retention in the University of its more distinguished and capable students."

Health of Edinburgh and Leith.

Among the notifications in Edinburgh for the past week were 20 cases of diphtheria, 7 of small-pox, and 336 of measles. There were 2 deaths from diphtheria and 9 from measles. There were no cases of small-pox reported in Leith, but there were 5 deaths from diphtheria.

Jan. 29th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

New Lunatic Asylum at Portrane.

THE overcrowding which exists in the Richmond District Asylum has rendered it necessary to construct an asylum at Portrane, which it is estimated will cost £200,000. Fifteen of the leading architects in Dublin were requested to send in plans for the asylum in question, with the understanding that each author of a plan should receive a sum of £40. Twelve architects accepted the proposal, and three assessors were appointed by the Board of Control to examine the plans sent in. These assessors were Sir A. Mitchell, Mr. George Hine, and Dr. Moody. They selected three of the plans which they regarded as of equal merit, the Board of Control to choose the first from among these three; the second to have £100, and the third best design £75. All the designs sent in have been exhibited at the Royal University of Ireland.

Benefit Societies, Cork.

A special meeting of the members of the St. Luke's Mutual Benefit Society was held last week for the purpose of electing a medical officer in the room of Mr. Philip Lee, L.R.C.P. & S. Irel., who had resigned. There were four applicants for the appointment, three hailing from England, but only two put in an appearance. Mr. William McMath, M.B. Royal University, was appointed, this being the fourth society to which he has been elected. A resolution thanking Mr. Lee for his past services was adopted amid applause.

The Club Fight at Cork.

Matters are progressing rapidly in connexion with the club fight. So far six of the clubs have accepted the reasonable terms of the medical men. Some time ago funds were subscribed for the purpose of defraying current and other expenses, but as it was felt that something more should be done, a meeting was held last Wednesday, and a sum of £450 was at once handed in. It is very much to the credit of some of the club practitioners that, though they have lost their clubs, they individually subscribed £15 and £20 to the medical war chest.

Resignation of Professor John England.

Professor John England, who for a period of over forty years occupied the chair of Natural Philosophy at the Queen's College, Cork, has retired on a pension. Many of the students who were pupils of Professor England now occupy high positions, both at home and in the colonies, and all entertain for

him the most cordial and genial feelings of friendship. He has been succeeded by Professor Bergin, M.A., who had a distinguished career at Trinity College.

Coronership of North Tipperary.

The office of coroner for the North Riding has become vacant, and there are six candidates for the post, three of whom are medical practitioners—viz., Mr. H. F. Powell, L.R.C.P. & S. Edin., J.P., of Nenagh; Mr. M. J. Quigley, L.R.C.S. Irel., J.P.; and Mr. J. C. Daly, L.R.C.P. & S. Edin., J.P., of Borrisokane. A like number are solicitors.

The Belfast Hospital for Sick Children.

The annual meeting was held on Jan. 25th, and from the report it appears that during the past year there were 11,438 extern and 403 intern patients. A class of senior students are attending the hospital clinics. The drainage at the Convalescent Home has been set right. The ordinary income for the year was £1956 13s. 9d. and the expenditure amounted to £1188 9s. 9d. The average cost per annum of each bed was £34.

Small-pox in Newry.

A serious outbreak of small-pox has occurred in Newry, the disease having been conveyed, it is thought, from Dublin. One case died on Sunday, another is in a very dangerous state, and eighteen patients are in the hospital. The schools are to be closed for six weeks. Vaccination is being carried out extensively, and a member of the Public Health Committee has given notice that he will move the adoption of the Infectious Diseases Notification Act. So far the disease is confined to the working classes.

Curious Inquest in Belfast.

An inquest has recently been held in Belfast which has caused considerable attention in medical circles. A man was brought to the Royal Hospital having sustained an injury by a fall, and subsequently died. At the inquest last week the resident staff reported that the cause of death was delirium tremens. This apparently annoyed the deceased's friends, and, their evidence being that he was not a drinker, the coroner adjourned the inquiry to Jan. 28th and ordered two outside medical men to make a post-mortem examination. Their evidence confirmed that of the house physician in the hospital, as they stated that the scalp wound present, which did not injure the pericranium, was not attended with any inflammatory action and the recently fractured collar-bone was in good position and perfectly set. They found the vessels in the head slightly congested, the right lung congested, a large quantity of fat about the heart, the liver 6 lb. in weight, congestion in patches of the interior of the stomach, the spleen twice its normal size, and the kidneys twice their normal weight. They believed (as was the view of the previous medical evidence given by the house physician of the hospital) that delirium tremens was the cause of death. The verdict was that death was caused by delirium tremens accelerated by a fall. One of the jurors disagreed with the verdict. One of the medical experts in his evidence stated that not only was the scalp wound not a severe one, but that it was not of such seriousness as to justify the staff of the hospital in detaining him. The medical experts thought that neither the scalp wound nor the fracture of the collar-bone was sufficient to cause the delirium tremens, but that the direct cause of death was delirium tremens. They could find nothing that would account for death except delirium tremens.

Jan. 29th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Idiopathic Polyuria.

DR. MARINESCO¹ has recently had under his treatment two boys (brothers) affected with the above disease. Their mother suffered from the same ailment, but in a slighter degree, during her pregnancies. The quantity of urine passed by each of the brothers averaged no less than twenty-eight litres a day. Analysis of the secretion revealed nothing abnormal beyond an excess of chlorides. One of the children

¹ Société de Biologie, Jan. 19th.

having succumbed to cerebral meningitis an opportunity was offered of a detailed examination of the nerve centres. The fourth ventricle presented to the naked eye an oedematous or, rather, gelatinous appearance. Histologically no alteration was discovered in the nuclei of the vagi, but the walls of the fourth ventricle were the seat of small hæmorrhages outside the vagi nuclei, and the neuroglia was considerably hypertrophied. The delicate fibrillæ of the ventricular walls had, moreover, disappeared.

Population Statistics of France in 1893.

During the year 1893 there were registered in this country 287,294 marriages, 6184 divorces, 874,672 births, and 867,526 deaths, a considerable improvement on 1892, during which year there occurred 18,825 births less and 8362 deaths more than in 1893. In other words, instead of a deficit of 20,041 we have on the credit side an excess of 7146 births. Of the children born no fewer than 76,562, or 8·8 per cent., were illegitimate—the highest proportion yet attained in France. The deaths comprised those of 449,682 males and 417,844 females, with a total mortality of 22·8 per 1000 inhabitants. Comparing the births with the deaths according to sex, it is found that with 446,957 births and 449,682 deaths there has been a loss of 2725 males, whereas an inferiority in the births has not prevented a gain on the female side of 9871. In thirty-six departments there was an excess of births over deaths, whereas in fifty-two departments the contrary was the case. Thus, in the Nord births exceeded deaths by 13,427; Pas-de-Calais, 8573; Seine, 4747; Finistère, 4403; Morbihan, 3080; Loire, 2437; and Corse, 2241. The principal offenders on the other side are the Rhône, Orne, Sarthe, Haute-Garonne, Hérault, Eure, &c. The number of divorces shows an increase of 412 over that of 1892, the proportion per 100,000 households being 81. Of the 6184 divorces the Seine department is responsible for no less than 1673—a proportion of 272 per 100,000 *ménages*. The Lozère department has the credit of having steered absolutely clear of the mode of relief placed at the disposal of *mauvais ménages* by M. Naquet. It is perhaps not generally known in England that the above-mentioned author of the Divorce Law, and former mentor of the late General Boulanger, was a distinguished chemist. His association with divorce proves him to have been fonder of analytical than of synthetical experiments.

Dr. Hergott.

This distinguished obstetrician (the father, not the son) was at the last meeting of the Académie des Sciences elected a corresponding member in the Section of Medicine and Surgery by 32 votes, as against 6 accorded to Dr. Laveran of paludic fame.

Prophylaxis of Broncho-pneumonia.

Dr. Hutinel has succeeded in almost stamping out broncho-pneumonia amongst his little patients at the Enfants Assistés affected with measles. The practical extinction of this formidable complication is due to the following precautions: every child is given sublimate baths; every sore, abscess, or crust of impetigo is carefully dressed; the nose and fauces are irrigated several times daily with boric solution or boiled water, and, finally, every child affected with broncho-pneumonia is promptly isolated.

Jan. 29th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Club Practice in Berlin.

THE position of the medical profession in Germany has been entirely modified by the "workmen's sick laws" (*Krankenkassen-Gesetz*). Formerly a young medical man began practice by treating the families of the working class till he became known and got patients among the better classes. Since the above law has come into force (1883) the workmen must form clubs, which are maintained by the contributions partly of the employers and partly of the workmen themselves. These clubs are obliged to provide the members with free medical attendance and medicine, and to pay a weekly sum if illness incapacitates them for work. The committees of these clubs, in order to pay as little as possible for the treatment of their members, appointed

a limited number of medical men and gave them a fixed annual salary on the condition that they attended the members free of charge. Thus club practice was withdrawn from general competition, and the position of the young medical men who were not fortunate enough to get club appointments became difficult. For the club members, too, it was a great drawback that they could not choose the medical man they liked, but had to apply to a practitioner in whom they had very often no confidence. No wonder that a combination, consisting chiefly of young medical men, made efforts to alter this state of affairs. They claimed that the united clubs should no longer appoint a limited number of medical officers with fixed salaries, but that every medical man who agreed with the club terms should be allowed to attend its members. They succeeded, indeed, three years ago, and a new system was adopted by some of the most important clubs. This system was that the clubs paid a certain amount (three marks a year) for every member, and that the total sum was distributed among the medical men according to the number of consultations they had given. All the medical men who were willing to treat club patients on these terms formed an association called the "Free Choice Society" (*Freie Arzt-Wahl*), into which every medical man could be admitted. At the end of 1894 more than 1100 Berlin practitioners belonged to the society. By this agreement club practice was, to the general satisfaction, open again to all the members of the profession. Also the sick workmen were very satisfied with the reform, and when more and more clubs adhered to the "free choice movement" it was expected that the old system would soon be entirely abolished. To the general surprise, the largest of these clubs (that of the unskilled workmen) declared at the end of last year that they would no longer admit every medical man without distinction to club practice. They asserted that many of the younger practitioners, to gain the favour of the patients, had ordered too many and too expensive medicines, that they had often extended the treatment too long, and that they were incapable of distinguishing the really sick from those who only feigned illness in order to be relieved by the club. These different things were said to have brought the clubs to the verge of bankruptcy. A still greater injury was done to the "free choice system" when the municipal authority, who have the legal control over the clubs, ordered them to appoint again a limited number of medical officers. Several did so and elected 150, but still adhered to the system of paying, not a fixed salary, but a sum according to the number of consultations. The importance of the club practice question will be clear even to foreigners if they consider that in some quarters of the town occupied by working people nearly 90 per cent. of the male and a large proportion of the female population belong to clubs. If the "free choice system" is given up definitely the result will be that the medical men who practise in these districts, but do not hold appointments, will make very little. We do not yet know the end of the matter, but the future of many Berlin medical practitioners depends on its issue.

Collective Investigation concerning Antitoxin.

An official investigation of the results of sero-therapy will be made by the Imperial Government. The hospitals of any importance throughout the empire are invited to take part. They must give a minute account of every case treated; if bacteriological examination was performed they must say if only Löffler's or other bacilli have been found; also they are asked if the curative effect of antitoxin was certain, probable, or not at all remarked. The answers are to be sent to the Imperial Health Office, where they will be collected and published. Another collective investigation will be made by the *Deutsche Medicinische Wochenschrift*, but this is not confined to hospitals only, but extends to all practitioners in Germany. Cards have already been sent to them with the following questions: How many of your patients were treated with, and how many without, antitoxin? How many in both these categories recovered and how many died? There are subdivisions for the ages of the patients, and the complications are also to be reported. The scientific and statistical work will be done afterwards by a committee, whose principal members are Professors Behring, Leyden, Heubner, and Ehrlich, and some other leading men.

A New Chair in the Medical Faculty of Berlin.

Dr. Heubner, Extraordinary Professor for Children's Diseases, has been promoted to the rank of Ordinary Professor. In foreign countries one scarcely understands the great

difference between an ordinary and an extraordinary professor, and English readers not acquainted with German university customs will not think this fact worthy of mention. They may be informed that only the ordinary professors belong to the board which controls the affairs of the faculty, nominates new professors and lecturers, promotes medical man, &c. They elect the dean of the faculty and the rector at the university, the highest rank in academical life, and are themselves eligible for these offices. Besides, they get fixed appointments from the Treasury and the fees for the faculty's degrees. The extraordinary professors have none of these advantages, either ethical or pecuniary, but earn only the salaries paid by the students for their lectures. Whilst the faculty may elect as many extraordinary professors as they think proper, the number of ordinary professors is strictly limited to the principal branches of medicine, anatomy, physiology, clinical medicine, surgery, and some others. The faculty boards are usually not much inclined to propose an increase of the ordinary professors, and Professor Henoch, the well-known predecessor of Heubner, (whose text-book has been translated into English), made long but unavailing efforts to have a new chair for children's diseases created. He suggested that this would be an honour conferred not on himself but on the specialty he taught. In many other universities—especially those of Bavaria, Saxony, and Austria—the number of ordinary professors is much greater than in Berlin, and the diseases of children, and diseases of the ear and of the skin have long since been found worthy to be represented on the faculty board. No doubt it would be still better if all these old-fashioned distinctions could be abolished and all professors have equal rights and equal duties; but this is, of course, not to be obtained without a total reform of university organisation.

Jan. 28th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Health of the Pope.

FROM Jan. 6th to 16th the Pope had a "leggero raffreddore" (slight cold), a return of the same indisposition which, as mentioned in THE LANCET of Dec. 15th, 1894, caused the suspension of all but private audiences on the part of His Holiness. On the 16th, however, the Commendatore Dr. Lapponi was able to assure inquiring visitors that the ailment was well nigh gone, a slight depression of voice being all that remained of the symptoms. Prudence still counselled the Holy Father's keeping his apartment, and only on the 17th did he resume his audiences, the first to be received being Monsignor Francica-Nava, the nuncio at the Court of Brussels, who was followed by Cardinal Galimberti, on important business relating to the presidential crisis in France. The responsibility resting on Dr. Lapponi and his coadjutor Dr. Topai is exceptionally great, particularly in times like these, when their octogenarian patient has the most delicate and difficult affairs on hand—the change from M. Casimir-Perier to M. Faure having disturbed negotiations approaching completion in France, and the substitution by Italy of the Franciscan for the Lazzarist missionaries in Abyssinia threatening unpleasant complications between the Tuileries and the Quirinal.

Sanitation and Hygiene in Italy.

The Direttore di Sanità Pubblica, Professor Pagliani, has just issued his report on the hygiene and sanitation of Italy during the last six months of 1894. Stated broadly, the health of the kingdom during that *semestre* has been satisfactory. There was but one serious epidemic during the six months, and that was the typhoid outbreak by which, in December last, Syracuse was so severely visited, when, in a few days, as many as 160 persons were attacked and twelve died. The phenomenon was tracked to its customary cause—the pollution of the water-supply. A thorough overhauling of the aqueducts and cisterns was instituted, and its completion has been followed by the practical disappearance of the malady from Syracuse.

Equally efficacious were the measures adopted by sea and land against the importation of cholera from its foci in Turkey, in Portugal, and on the French Mediterranean littoral. In fact, all danger from European ports having been averted, the Direzione della Sanità Pubblica was able, in November last, to suspend *sine die* the medical visitation and disinfection of suspected ships hailing from most of these harbours. These measures, however, have still to be enforced on vessels coming from the Black Sea, from the colonial French ports, from those of Russia and of Roumania on the Danube, from the Sea of Marmora, from the Aegean and from the North African littoral (excluding Tripolitania), and from Brazil. The various sanitary stations in the Adriatic, the Ionian Sea, and in Neapolitan and Tuscan waters (comprising the admirable one described in THE LANCET of Oct. 20th, 1894) have all done good service, the disinfecting processes particularly being carried out with promptitude and thoroughness. The "risanamento" (sanitary rehabilitation) of Naples, to turn to another topic, in spite of interruptions and restrictions due mainly to financial difficulties, is now on a more effective footing, and the Direzione della Sanità Pubblica is in hopes of registering still more progress at the close of the next *semestre*.

The Conditions of Child Labour.

The conditions of child labour in the subterranean industries, especially the sulphur mines in Sicily, have engaged the Ispettorato delle Miniere (mining inspectorship) in an important study which has this day been made public. The gravity of this question is known to readers of THE LANCET. On March 10th, 1894, you called attention to the fact that in Sicily, for example, in the province of Caltanissetta alone, the physical deterioration of the young is deplorable. Dr. Mosso, the Professor of Physiology at Turin, as the result of investigations on the spot, revealed the appalling results of mining labour in the island, results which explain the fact that in the four years from 1881 to 1884, out of 3672 young "solfurari" of Caltanissetta examined by the officers of the military levy only 203 were found fit for service in the army. The "study" just issued by the Ispettorato—the substance of which was brought before the recent International Congress at Milan for the prevention of casualties and deteriorating influences connected with labour—does not confine itself, however, to Sicily or to sulphur mining, but includes all subterranean operations throughout the peninsula and its islands, such as the lignite mines of Umbria, Tuscany, Sardinia, Lombardy, and Piedmont; the lead and zinc mines of Sardinia; the iron mines of Elba; the marble quarries of the Apuan Alps; the "pizzolana" pits in the Roman and Neapolitan "campagna"—in short, all the industries pursued underground, including even the tunnelling works in railway construction. The monograph, for such it really is, covers too vast a space to be more than referred to here. But its data, its conclusions, and its practical recommendations will be found of interest in other States besides Italy—wherever, in fact, labour is carried on removed from the light of day.

Insubordination among Students.

Undergraduate insubordination has lately assumed epidemic proportions throughout Italy—Rome, Pisa, Bologna, Padua, and minor schools like that of Parma, having become the scene of riotous outbreaks on the part of the students. To our British ideas there is far too pronounced an interest in current political affairs among Italy's academic youth, any public incident or "new departure" in the legislative sphere sufficing to engage the undergraduates in keen personal controversy, sometimes with their teachers, sometimes with this or that Education Minister, invariably (I may add) to the prejudice of their studies and the grave breach of that continuity of work and discipline without which academic qualification can never be sound. For the present, the worst of these outbreaks is over; but there is no saying when a new wave of excitement or enthusiasm may reproduce the turmoil and the anarchy so recently running its disastrous course throughout the universities. When, in 1860, Italy became united and independent, her great Minister, Massimo d'Azeglio, said: "Now we have to make Italians!" Certainly the remark, after a whole generation of "unity" and "representative institutions," has lost none of its sting, if the academic history of the last few weeks has any practical bearing on the future of young Italy.

Jan. 21st.

THE INDIAN MEDICAL CONGRESS.

THE SECTIONS.

OBSTETRICS AND GYNÆCOLOGY.

DEC. 24th, 1894.

Presidential Address on the Influence of Race and Climate upon Obstetrics and Gynæcology in India.

[SURGEON-MAJOR H. PEERS DIMMOCK, Professor of Midwifery, Grant Medical College, Bombay, delivered his presidential address. After a preamble dealing with the importance of the subject and the difficulties incidental to its treatment in an Oriental country, he proceeded to the consideration of puerperal fever, saying:]

"Since Professor Semmelweis first placed us in possession of the axioms of puerperal fever there has been accumulated a mass of evidence to demonstrate their truths, and fresh knowledge had been added to them, especially by the discovery of the antiseptic system of Lister. But though the ideas of all authorities are fairly well defined there are still many effects and conditions of puerperal fever and points of difference that are hard to reconcile. This is especially the case in a country like India, which teems with forms of pyrexial diseases that are liable to complicate the pregnant and puerperal states. To indicate all forms of puerperal fever as puerperal septicæmia, whatever the infective cause and however much the symptoms may vary, is alone sufficiently confusing when we are brought face to face with their actual protean clinical facts; and, on the other hand, to seek to differentiate each and every kind of puerperal fever according to its features, whether of cause or effect, would lead us into an interminable phraseology that would be too awkward for any practical purpose. The old familiar term 'puerperal fever' as a main distinctive indication is rendered sufficient for all purposes by the affix of a descriptive adjective for the special condition or cause associated with the pyrexia of the puerperium, which, after all, is the generic meaning of puerperal fever. Thus the words 'traumatic, septicæmic, and pyæmic puerperal fever' would describe fairly well the form of puerperal pyrexia that was associated with traumatism, septicæmia, or pyæmia. Any local effects can, at the same time, be described as complications, and we should thus have a designation like 'traumatic puerperal fever with pyo-metritis,' and so on. To eliminate the special characters and peculiarities of these and other complex puerperal fevers we require a very extensive knowledge of their clinical features, and in India we are confronted with so many kinds of the fever type of disease that such an inquiry is sure to be full of immensely interesting and intricate possibilities. Clinical observation and deductions therefrom are always most attractive, and have been naturally the principal methods of elucidation of disease throughout all time of medical knowledge. They demand the first attention of the physician, and nowadays, waited on by pathology and its youthful hand-maid bacteriology, they are yielding most fruitful results. In these rapidly progressive days we are continually on the outlook for some fresh means of divining the actual causes and conditions of disease, and those occurring in the pregnant state and the puerperium are so environed by their own peculiar accompaniments that there is a separate and special field for the study of them both clinically and pathologically. In a research into the causes and effects of puerperal fever in India we are confronted not alone with special disease entities, but also with the many conditions peculiar to the country itself—of season and meteorological events, of race, of surroundings, of habits, of intercurrent disease, and of the preliminary effects of the pregnant state under such conditions, in all of which I can only suggest what a large field there is for philosophical, thoughtful, scientific, and useful inquiry, especially to those members of the profession who actually practise amongst the people and are intimate by race association with their modes of life and other influences. In a tropical climate the main influence would, of course, be that of the high temperature of the air, by which all developments and changes are brought about with a greater rapidity, so that the tissues become less stable, less hardy, and so tend to disintegrate quickly when once a rift is opened in their continuity. The extreme changes of intense dry stimulating heat in the summer and of a depressing heat that comes with the onset of the monsoons present aspects of variation, apart even from acclimatisation, in the organisms of all who are subject to them, and still more of those whose temperaments are liable to an easy divarication of the physiological

equilibrium either towards depression or exaltation. As examples of the differences of disease types under such circumstances may be taken the sharp attacks of fever which occur in the drier seasons of the year and the low forms of continued fever and malarious cachexia with engorgement of the abdominal viscera, especially of the spleen, such as take place in humid states of the atmosphere and damp climates. Frequently the slow development of malarious cachexia produces in the pregnant woman a form of pernicious malarious anæmia which is characterised towards the end by intense anæmia, œdema, and an enlarged spleen and liver, for the sluggish circulation and nervous debility encourage congestion of the organs. Race may show its influence in the various tendencies that are developed out of evolutionary characteristics, as, for instance, the neurotic type, rendering the woman more susceptible of nervous impressions and reactions, often altering the characters of disease by super-added nervous phenomena, such as high temperature quickly subsiding. Habits of food, of drink, and of luxury are worthy of reflective consideration, and it may be accepted as a fact that pregnant women whose food is of a vegetable and non-stimulating kind will have less stamina in enduring prolonged pain and exhaustion, but will recover more quickly from ordinary trials, than those whose food is of a more generous description, while again the latter will be more liable to inflammatory reactions and rapid tissue changes, such as sloughing from traumatic injury. The surroundings of pregnant and puerperal women are manifold in their effects, and include those of the room, the house, the village, and the town, septicæmic, zymotic, and malarious puerperal fevers being the most likely outcome of dangers from these sources.

"I have had the usual experience of most inquirers in being baffled at the outset by forms of puerperal fever that I have had to deal with in India, and what impressed me most in the first instance with some of the cases was their unusual and surprising resistance to rigid antiseptic and aseptic precautions. A study of a series of temperature charts and the effects of various treatment on the temperature gave the true line of explanation. When once the clue was given the opening of some of the hidden processes was shown, so that I venture to tabulate certain forms of complex puerperal fever as follows:—

1. Malarious intermittent puerperal fevers.
(L) quotidian; (B) tertian; (Y) quartan.
2. Malarious remittent puerperal fevers.
3. Thermic do. do.
4. Dysenteric do. do.
5. Syphilitic do. do.

"I have no doubt that others will be added to their numbers as the science of medicine progresses and wrests from the chaos of uncertainty the many forms of Indian fevers. The protozoic causes of these fevers may develop in the pre-pregnant or the pregnant state, and be carried on into the puerperal state to be further impressed with a septicæmic pyrexial element, which is the result of the condition of the tissues and systems of the puerperal patient, rendering the unusual secretions and excretions more liable to the action of infective agents; or these causes may be latent in the system, manifesting no symptoms until they are excited to action by the onset of labour or roused to a more powerful influence by a septicæmic pyrexia. To deal with the group of the malarious forms of puerperal fever I submit cases with their accompanying charts. Many of you may be familiar with an experience that pregnant patients in this country who contract malarious fever, or whose systems are inoculated with its organisms, are very resistant to treatment for malarial fever or cachexia, either because the blood and tissues of the pregnant women are very retentive or reproductive of the disease factors, or because they are specially vulnerable to and ineffective in repelling their ravages. How often it happens that a pregnant woman suffering from malarious fever is treated by all the known methods, which produce no yielding of the fever for some time, and when the pyrexia runs high miscarriage is sooner or later brought about. The quinine may here be wrongly blamed for the mishap, which was in reality due to the overheated blood current and to the poisons circulating in it, and I have elsewhere protested against this shibboleth of the objection to use quinine in doses that are adequate for the control of the disease. At the same time we must not forget that sometimes malarious fever is not affected by quinine, and that the system may also be inoculated with previous treatment by

that drug, so that it fails to give the expected result. It may be some days even before an ordinary attack of ague in a pregnant woman can be controlled, and if the case is allowed to go on without treatment the disease gets such a grip of the patient as to be uncontrollable, and if labour or miscarriage results an additional puerperal septicæmia is an inevitable result. We are also all familiar with the sudden appearance of malarious fever coincidently with a severe shock to the system, such as a fracture of a bone, the passage of a catheter, or an overwhelming emotion, and recollecting that the dilatation of the os uteri is often accompanied by a rigor I have attributed the sudden accession of a high temperature at the commencement of labour to a disturbance of latent malarious poison by the vascular, nervous, and tissue changes wrought by the mechanical process of dilatation. It is difficult to account in any other way for the sudden appearance of these fevers at such crises when they have not been preceded by any signs of a taint lurking in the body, and I believe that the organisms are really latent and that their sudden activity is because the balance of nervous control is disturbed by the event of labour, the vitality of the cells and leucocytes are diminished, and their ranks are thereby thrown open to the invaders, because the reflex irritation to the nervous centres causes through the trophic nerves changes in the metabolism of the body, and through the sympathetic nerves changes in the circulation which facilitate such morbid processes. It is the same with malarious fevers that develop after labour in association apparently with the stimulus to the plasmodia of slight or severe puerperal septicæmic pyrexia, and in these instances the puerperal fever will be established with the thread of malarious fever running through it and giving a distinctive character to the temperature record, for the treatment of which complex condition it is necessary to combine methods applicable to both the diseases. Further, whenever malarial fever is developed in the puerpera there is a liability to what may be called an autogenetic form of septicæmia as a result of the high temperature of the malarial fever, for the lochial secretions decompose rapidly within the genital cavity, and their poisons are absorbed into the system, so as to produce the usual septicæmic effects in addition to those of malaria, and thus to cause a continuance of pyrexia during the intervals that would be remissions of the malarial fever, and to exaggerate the high temperature of the pyrexial stage of the malarious attack. Very high and alarming temperatures are developed in this way. Again, puerperal women who have malarial cachexia may have progressed favourably even beyond the first week, when they expose themselves to a chill, and this is followed by the typical phases of the rigor, of the pyrexia and sweating stages of ague. The lochia become offensive, the temperature is continuously high, and there is an intermittent recurrence of the ague and increased pyrexia. It takes several, sometimes many, days before recovery is brought about, while if proper measures are not adopted the case may end fatally. In all these cases, associated with malaria of whatever kind, we have not only general effects to deal with, but also those local effects that are inevitably associated with the traumatism of labour. The lowered vitality of the tissues makes them very prone to take on a sloughing or even gangrenous character, and such conditions are not only resistant to repair and will heal slowly, but add a further and serious danger to the case from a multiplication of poisonous agents. If no treatment of the constitutional state is adopted their ravages will increase to a terrible extent, so that I have seen cases of malarious cachexia in the puerpera where the genital passages have been in a gangrenous state throughout their whole area; consequently when artificial traumatism is produced by the use of instruments particular precautions are necessary to guard against such effects, and although there may be no apparent symptoms most rigid attention should be paid to the local antiseptic treatment. Another effect of malarious cachexia and of malarious fever during pregnancy is to cause a placentitis, from which the placenta becomes adherent, and so adds a further danger to the case at labour time. The shock of manual detachment may set up the pyrexia of malaria or there may be infection from without by the operation. Such patients often complain of excessive tenderness over the uterus during pregnancy, which is no doubt due to the inflammation that is going on. Another effect of malaria in the puerperium is to produce intense neuralgia of some of the sexual organs. It may be the uterus that is thus affected, in which case it is probably caused by some inflammation of the nerve filaments com-

municated from a placentitis, or an actual primary neuritis of malarial origin, and the patient may suffer great pain, especially in connexion with the after-pains. I have found the uterus in these patients to be excessively tender, and the condition has mostly yielded at once to quinine and anti-neuralgic drugs. I can recall one case of acute neuralgia of the ovary which followed a miscarriage. The patient did well in all respects except that at a regular hour every afternoon she suffered from acute agonising pain in the left ovarian region. It yielded at once to large doses of quinine. Post-partum hæmorrhage is also very likely to occur, mostly from the effects of the placentitis, but also in consequence of the state of the blood, of heightened blood pressure, and of the defective contractile power of the uterine muscular tissue. Diarrhoea is a frequent occurrence and is of great importance. In all conditions of health or disease in people living in India, whether native or acclimatised, there is a primary climatic potentiality towards diarrhoea. A chill, an irritant, or disease are likely to be accompanied by it in ordinary individuals, and in puerperal fever particularly this natural tendency is exaggerated by the secondary morbid and derivative tendency of the system to relieve itself of the toxæmia through the mucous membrane of the intestines. Accordingly the usual dose of castor-oil will frequently start a severe diarrhoea, and sometimes almost choleraic symptoms are caused by what seems a slight cause. Rheumatism is an occasional complication: the connexion between rheumatism and malaria is outside the present subject, so I will not discuss it. Mania is also a not infrequent sequel and has partly to do with the state of health and partly with the high temperature. The higher the temperature the more likely are the psychological centres of the brain to be injured and disorders connected with them to follow. The fœtus is, as a rule, not particularly affected, except in nutrition, and so suffers from fever at birth only in occasional cases, and this is probably due to the resistant and destructive power of the placental structures, which thus guard the entry of the foetal area from deleterious matters. A similar result occurs in some cases of syphilis contracted during pregnancy."

[Surgeon-Major Dimmock then quoted cases of various forms of malarious puerperal fevers with their treatment, laying special stress on the point that quinine should be administered hypodermically in order to avoid the effect upon the digestive tract. He continued:]

"The next series of puerperal fevers is that of the dysenteric form, which arises in connexion with a true dysenteric attack. The dysentery itself generally originates during pregnancy, either at full term or earlier. In the former labour and in the latter case abortion or miscarriage are very likely to occur, and so we have a puerperal condition with the dangerous concomitant of very poisonous alvine discharges. Infection of the genital passages from these produces an extraordinary disease of the puerperal fever type. Dysentery itself is very obstinate in pregnant women, and there are no doubt turgescence of the mucous membranes and changes in the circulation, which make the disease persistent. It is also desperately resistant to remedies, so that a dysentery of an acute form in a woman near the end of pregnancy is peculiarly dangerous in this respect as well as from the further risks of exciting premature confinement and of following up its primary havoc by an infection of the system with the faecal toxins. The most careful treatment often fails to prevent these consequences, and sometimes, when the case has taken a favourable turn, it is liable to relapse. Much may be accomplished by repeated large doses of ipecacuanha, opiates, sedatives, and antiseptics internally and externally; ipecacuanha is sometimes very well borne, so that I have been able to give thirty grains twice a day. No treatment is effective unless the food is absolutely unirritating, and peptonised milk and lime water are the only diet that serves the purpose. I have included an example of another series of cases, those of the syphilitic, because I have found peculiar results in the puerperal state in women who are strongly tainted with the specific disease.

"CASE 7.—M. M—, aged twenty, Hindu, para, admitted in labour on April 26th, 1894, and in consequence of a tedious second stage was delivered by forceps on the morning of the 27th. There had been no complication of pregnancy, but the patient had appearances on her body which indicated syphilis. On admission the temperature was 102.5°F. and the pyrexia continued after delivery. The case was treated antiseptically for simple septicæmia, and somewhat improved, but again relapsed. On the twelfth day of the disease iodide of potassium and santolin powder were

given, with a gradual improvement, but the patient still remained feeble and prostrate and in bad nutrition until inunction of mercury was resorted to on the twentieth day of the puerperium. The improvement was then rapid and satisfactory, and the patient was discharged well on June 11th. This case suggests many questions. Why puerperal fever should develop under such conditions, and whether it is puerperal fever, whether it is a climatic effect on the syphilitic patient, whether the syphilis stirs up an irritative fever in the system, or does the syphilis render the body more susceptible of septicæmia, and the septicæmia more persistent than usual, until specific remedies are used. In cases of puerperal fever of a continuous type associated with increasing cachexia, where the child shows also faint symptoms of congenital syphilis, it is always advisable to administer specific remedies. Of other forms of Indian puerperal fever the thermic is the one most frequently met with, and of course its main characteristic is intense and resistant hyperpyrexia. It is usually the sequel of pyrexia occurring before or during labour, although it may occur during the puerperal state, being most liable to happen on the third day in connexion with the usual slight fever which results from any affection or lacteal disturbances on that day. It may be associated with puerperal eclampsia, and cases of this kind that occur without albuminuria indicate an intense congestion of the meninges. Complex cases of puerperal fever in association with other diseases of the pyrexial type must sometimes occur."

[Surgeon-Major Dimmock paid an eloquent tribute to the value of good nursing and concluded:]

"Ne let the man ascribe it to his skill
That thorough grace hath gained the victory.
If any strength we have, it is to ill,
But all the good is God's, both power, and eke will."

PROCEEDINGS IN SECTION.

DEC. 26TH, 1894.

The following are abstracts of papers read at the Congress:—

Malarial Influence in Abortion and Sterility.

MR. ARTHUR J. WEATHERLY, M.R.C.S. Eng., L.R.C.P. Lond., in his paper under the above title said:—"From my experience in Africa, Florida, and India, I do not think sufficient stress is laid on the malarial influence in abortion and sterility. In my practice I have had the following cases:—

	Confinements at term.	Abortions.
England	56	2
Healthy parts of South Africa where malaria is unknown	35	2
Unhealthy parts of Africa	40	20
Florida	30	22
India	60	28

And a large proportion of these cases, though living in malarious districts, did not abort at times of an attack of fever—in fact, in very many cases malaria only showed itself in the habit of abortion. I have also noted that a very much larger proportion of women are sterile in malarial districts than in others, and that if they reside many years this sterility becomes permanent, whereas if they leave before too long a time has elapsed they bear children. Of course, in this latter class I do not include those who, miscarrying in malarial districts, bear children in non-malarial climates. Perhaps, as this paper has to be short, the quoting of two typical cases will be sufficient. I would like the experience of others in malarial districts on this subject, as I think its importance is not sufficiently recognised. A woman had frequent miscarriages in the plains. She was constantly in malarious districts. She was treated by various surgical and medical measures, including scraping out the uterus, both in India and in London. On her return to a malarious district, however, she invariably miscarried—generally in the third month. I saw her early in her fifteenth pregnancy (after ten following miscarriages in the plains), and advised her to go at once to the hills and stop there, giving her a tonic of citrate of iron, quinine, and strychnine, and enjoining recumbency for ten days at a time when her period would have been due if not pregnant. She went safely to term. Another woman had lived for years in a malarious district, and had never been pregnant. The first year on coming permanently to the hills both husband and

wife suffered much from fever, but in the second year both were in good health, and the woman became pregnant and went safely to term. These are only two instances of very many. The influence of malaria on abortion and temporary sterility is still more marked in the very deadly malarious climate of Florida, where I saw twenty-two cases of abortion to thirty confinements at term, and ten cases of temporary or permanent sterility in a period of two years in a very small district. In a malarious strip of coast country in East-south Africa sheep and cattle constantly abort, and, in fact, the natives have recognised this so well that they keep their breeding stock inland and only send their stock into this strip of country to fatten. In this country there were no Europeans, but abortions were frequent among the native women, though I could get no figures as to the proportion. A large number of women who have been in malarious countries, even if they do not abort, suffer very much more when pregnant at the times when their period would have come on than is common with women who have not been in a malarious country, and require very strict precautions as to recumbency, &c., at such times. In such cases I have found that giving quinine, rather than tend to bring about abortion, certainly tends to ward it off. Though my experience does not extend over very many years, it embraces malaria in very different climates; but in all with the same effect in bringing about abortions and sterility, and proves a danger in the former case, which, I think, is not sufficiently recognised and guarded against."

DEC. 27TH, 1894.

Biliary Cirrhosis of Children.

MR. JOGENDRO NATH GHOSE, L.M.S., read a paper on the above subject. He said: "Under this title I venture to lay before you some facts connected with what I may call a new disease, which has lately appeared among the children of certain classes in Calcutta and other parts of Lower Bengal. On account of its generally unsuccessful treatment and fatal termination it has of late drawn considerable attention and been the subject of serious thought in the minds of medical practitioners and the general public. I call it a new disease, because it has not yet been treated in any of the current books on practice of medicine. The short descriptions that have appeared in some of the recent medical works of a similar liver complaint are very vague and imperfect, and they do not seem to refer exactly to the particular disease now under discussion. It also escaped the observation of early European practitioners, who in most subjects have left behind valuable records of their Indian experience, and until twenty years back it scarcely drew the attention of our old and experienced medical brethren. The literature on the subject of this disease is, therefore, still very meagre. The peculiar features of the disease are that its onset is insidious, that it usually prevails among infants under the age of one year, and that it seldom attacks children after they have passed the third year. The attack generally commences on the seventh or the eighth month, chiefly at the period of weaning or the mother's next conception. The children of some parents are particularly liable to the disease. In one family I have observed fourteen children of the same parents die one after the other. Cases of attacks in the third or fourth month, or even a few days immediately after birth of the child, have also been noted. Children in Calcutta, as well as in the districts of Bengal, whether malarious or non-malarious, are equally subject to it. It makes no difference between the children of the intemperate, the sober, or the teetotaler. It spares neither rich nor poor, though the well-fed children of the wealthy and the middle classes are more liable to it than the ill-fed children of the poorer class. Muhammadan and Eurasian children suffer less than the Hindus. Hardly any cases are seen among Europeans. Children who were never put, or put for a short time only, to the mother's breast, and fed with cow's, goat's, or ass's milk, or with different kinds of artificial food, enjoy no immunity from this disease. In those families where the disease prevailed I noticed a few children escape apparently, being nourished by healthy wet-nurses. When the disease was first noticed in Calcutta more cases were found among male than among female children; but of late the proportion seems to be less, and more female children than formerly now come under the notice of practitioners. Still, I shall point this out as a peculiar feature of the disease. Another peculiarity noticed is that the female children mostly attacked are usually the

first-born of the parents, and who are necessarily the objects of great care in a family. It has been observed that a female child escapes the malady after the successive deaths of several males that preceded her, though again the next male child succumbs to it. Children of very healthy parents are not exempt, and the disease appears to be quite unconnected with long-standing purulent discharge, scrofula, syphilis, malarious fever, or any chronic constitutional disease. In a family of several brothers living in the same house and under exactly the same conditions as regards food, it is rare to find the children of more than one of the brothers affected with the disease. In one family of three brothers living together under the Hindu family system one brother lost fourteen children, most of whom died about one year old, while the ten children of the other brothers remained quite healthy. This is the rule, but exceptional cases have come under observation in which the children of two brothers living together were affected by the disease, of the children of a brother and a sister living apart being attacked, and of the children of two sisters living in different families having suffered from the disease. It has also been noticed that in some cases the later children of some parents escape the disease after the earlier ones have, one and all, died of it. The enlargement of the liver is gradual, and is unattended with pain. The subsequent contraction is, however, rapid. The termination is generally fatal, death being mostly due to cholæmia. The disease runs its course in from three to twelve months, though one case has been known to end fatally within a fortnight of the attack, and the patients in two other cases which came under my observation lingered on for three years, and in these cases change of climate was tried in vain. In my experience, out of about 400 cases only 6 recovered. The diagnosis in the case of 3 is, however, open to doubt. Of the remaining 3, one child was sent out for change at the very commencement of the disease, and two recovered after the first symptoms had fully manifested themselves, but in none of these cases was there persistent jaundice, which in my experience is a fatal sign."

[Mr. Ghose then sketched the history of the recognition of the disease.]

"The disease may be defined now as a painless enlargement of the liver, hard and resistant to the feel, beginning with slight fever, occurring in children only, and terminating almost invariably in death. The onset of the disease is so very insidious that, as a rule, nothing is noticed by the parents until the liver has attained a considerable size. To my knowledge qualified medical men of considerable experience failed to detect the disease at the early stage in cases even of their own children. The early symptoms which attract the mother's notice are nausea, occasional vomiting, sallow complexion, warmth of hands and feet, and a certain amount of constipation with straining at stool. The child also refuses food, gets irritable, loses its cheerfulness, wishes to lie down on a damp ground, and gets a little fever towards night or early in the morning. Some thirst also is noticed, as the child looks wistfully at the sight of water and tries to lay hold of the vessel containing it. A slight icteric tinge is also sometimes observed in the eyes. When the child is brought under a physician's observation the liver appears enlarged, at times so considerably that it extends as far as the umbilicus or even beyond it to the iliac crest. The skin is harsh and dry, there is slight jaundice, marked constipation, with white stools and bile-stained urine. Ascites sometimes occurs, and later on jaundice becomes intense. With the appearance of this symptom contraction of the liver proceeds with extraordinary rapidity."

[Mr. Ghose next discussed the etiology, being of opinion that the disease always arose from improper feeding and mal-assimilation. He laid special stress upon the practice of mothers suckling their children when pregnant, and in the case of bottle-fed infants upon unwholesome milk. Irregularity in feeding and over-feeding were also cited. Predisposition was mentioned as being a deciding cause, and a number of cases quoted showing that the disease attacks the children of only one wife, while those of the others by the same husband enjoy a perfect immunity. Mr. Ghose then discussed the diagnosis, differential and otherwise, of this disease, pointing out that it was especially a disease of large towns. The duration was from three to nine months. The prognosis was very unfavourable, and treatment, whether dietetic or therapeutic, had been so far unsuccessful. For the pathology and morbid anatomy he referred to an article by Mr. J. B. Gibbons in the Scientific Memoirs, Part VI., and concluded by an appeal to the profession to try to discover

some remedy, since there was nothing in the pathology to justify a hopeless prognosis.]

Biliary Cirrhosis in Children.

Mr. E. MACKENZIE, V.H.A.S., in a contribution under the above title, said:—"When I held charge of a dispensary in North Canara, a tract of country on the south-western coast of the Bombay Presidency, during the years from 1872 to 1880, I had extensive opportunity of seeing, and of verifying by post-mortem examinations, a fatal form of cirrhosis of the liver occurring in children from birth up to three or four years of age. About twenty applications were made to me every year, either for the purpose of eliciting an opinion or for treatment, or that post mortem I would remove the liver so that it might be destroyed separately from the body, under the superstitious belief that the diseased organ was a turtle¹ (a resemblance imparted to it by the shape and appearance of the organ, with the gall-bladder representing the head of the animal), endowed with distinct life, and needing a distinct process of cremation for its extinction. The disease was so well known and generally so easily recognised by the parents that once its existence was established they abandoned all hope of the child's life being spared. As this paper must necessarily be brief I will very concisely give the symptoms and post-mortem appearances observed by the naked eye and microscope; then refer to the cause as being very obscure and confessedly the weakest part of the paper; and, lastly, allude to the very unsatisfactory results achieved by treatment. If by putting forward this paper any good may result in elucidating the cause and the attainment of a more successful plan of treating the disease I should be very glad. The symptoms set in slowly with feverishness, high-coloured urine (staining the clothes a deep yellow), jaundice, anasarca, enlargement and induration of the liver and spleen with slight tenderness over these organs, liver enlargement downwards very considerable (involving both lobes equally), respiration hurried, prominent abdominal subcutaneous veins (especially on the right side), constipated bowels or scanty yellow faecal motions, in a few cases hæmatemesis (in one leading to an abrupt fatal termination) and in others melæna, conjunctivæ bright saffron, and the eyelids and scrotum slimy and oedematous, the latter so intense sometimes that I have been tempted to puncture and let out the yellow-stained serum. The duration of the disease is from one to four months, in cases of shorter duration death being due to hæmatemesis or coma from blood poisoning. The urine is dark and scanty, often thick, generally free from albumen; the bile acids are absent, and there is no leucine or tyrosine to be detected in it. The tissues were deeply jaundiced, the liver was not shrunken or hobnailed, of increased dimensions generally, more solid and firm, both lobes equally affected, surface granular or papillated, of yellow colour from bile-staining, and with predominance of fibrous tissue. On section it is hard and tough, the lobules being almost obliterated from pressure of fibrous growth in the interlobular tissues, around the interlobular bile-ducts, and extending into the lobules. The capsule did not appear thickened, and, although smooth to the touch, presented a granular or nodulated appearance from irregular deposit of the newly formed fibrous tissue within the organ. The lobules were atrophied and surrounded by fibrous tissue, which had permeated the organ throughout, invading and destroying the cells, some of them entirely. The gall-bladder was almost empty, and there was bile-stained serous effusion into the peritoneal, pericardial, and pleural cavities, and into the subcutaneous cellular tissue. The kidneys generally were congested and softer than usual, the capsules peeling off easily; they were sometimes mottled, but not contracted. The spleen was enlarged and more friable than usual. With the opportunities afforded, and in the face of facts before me tending to lead to some certain deductions, I regret I cannot satisfactorily connect cause and effect. Malaria, syphilis, climate, diet, and habits of the people have been considered, but none can be pointed to conclusively as a cause. That the disease is more prevalent in Canara than in other districts of the Bombay Presidency I feel justified in asserting from the fact that, during a service of twenty-six years located in Bombay, Guzerat, Canara, Aden, Deccan, and Sindh, to one case that may have been treated for a malady resembling this in nature in other parts of the country, twenty or more have been seen in Canara during the same time. The disease has been confined to Brahmin

¹ After which it was called "Kurmrogh."

children, or in those approaching in habits and mode of living to the Brahmins, but why it should be peculiar to them is not clear. A single instance was not found in a Sudra, Christian, or Mussulman, although all lived very much alike, partaking of very much the same kind of food, as rice, fish, pulse, vegetables, and condiments, excepting for a few sects of Brahmins (who formed only a fraction of the bulk of the population), who did not use fish. Looking upon infant feeding as a likely cause, there is nothing to show that the mode is more faulty in Canara than it is anywhere else. Here, too, the children have to battle against unsuitable food given them by their parents, like balls composed of grain flour and seasoned with aromatics kept prepared for weeks and used as required. The early administration of starch and the free use of spices and condiments at a tender age tend no doubt to set up fermentative changes in the stomach and become chemical irritants. Brahmin women in childbed adopt a diet which may conduce to the disease in the new-born infant, in whom it has been seen. They restrict themselves to the use of a strong decoction of black pepper to allay thirst, abstaining from liquid of any other kind, and as food use balls made up of boiled rice, ghee, and coarse sugar. Is it possible that the pepper here, acting through the mother's milk, might start irritation in the infant liver? Canara is a malarial district—heat, vegetation, and moisture tend to make it so in a pre-eminent degree; but the disease is as common on the sea coast as it is in the interior, where one would suppose malarial influences would be greater. Malaria, moreover, is not peculiar to Canara—then why should the disease be more prevalent there than in other parts of the country? Evidence pointing to syphilis as a cause is also wanting, and alcohol is out of the question in children so young. The people in those parts do not indulge to any excess in alcohol, tobacco, opium, or hemp, their favourite luxuries being *pān* and *supari* (betel leaf and areca nut), which can hardly have any connexion with the disease as a cause. The treatment has consisted of counter-irritation over the liver, the application of ung. pot. iodi. with ung. hydr., or tinct. iodi. Internally purgatives, calomel or hydr. c. creta, slowly administered and continued for some months; potas. iodic., ammon. chlorid., with acid. nitro-muriatic dil., syrup. ferri iodic., quinine, diuretics, and diaphoretics. All have failed."

Obituary.

JAMES LAWRENCE, M.D. ABERD., L.R.C.P. AND F.R.C.S. EDIN., J.P.

WE regret to announce the death of Dr. Lawrence, which took place on Jan. 10th, after a lingering illness of diabetic origin, at his residence in Cumnock, Ayrshire. Dr. Lawrence had an extensive local practice, which developed from his appointment many years ago to be surgeon to the Lgar Ironworks. He was born about 1828 in Kirriemuir, Forfarshire, and at an early age entered as a student in the Faculty of Arts in Aberdeen University. He subsequently attended the medical classes, and after the usual curriculum qualified as L.R.C.S. Edin. in 1849. Before long he commenced practice in Ayrshire, as already mentioned. The professional success which he obtained, together with his habits of studious diligence, induced him in 1860 to enlarge his medical qualifications by graduating as M.D. of his university and taking the diploma of L.R.C.P. Edin. In 1867 he became a Fellow of the Royal College of Surgeons of Edinburgh. Dr. Lawrence was very popular in the district, and his benevolent disposition endeared him to the poorer class of his patients. His death leaves a notable blank in local society.

A VACANCY in the office of obstetric physician to the Manchester Royal Infirmary caused by the retirement of Dr. Lloyd Roberts has been filled by the election of Dr. Archibald Donald. Dr. Donald's long connexion with St. Mary's Hospital, Manchester, is looked on by his colleagues as a guarantee that good and efficient teaching of the students will be forthcoming from him.

Medical News.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS IN IRELAND: CONJOINT SCHEME.—The following have passed the Final Examination:—

A. S. L. Burke, J. Cairns, M. A. Corcoran, J. H. J. Davys, M. Delaney, J. Fleming, W. A. Gordon, R. D. Jephson, T. O. Jordan, H. G. Martin, W. F. A. McCann, W. Stratton, and J. H. Walsh.
Passed in Medicine.—J. W. Griffin, E. C. Hodgson, and E. J. K. Hogan.
Passed in Surgery.—C. Cavenagh, J. T. Harold, E. C. Hodgson, E. J. K. Hogan, H. T. J. Kennedy, and J. F. Sheppard.
Passed in Ophthalmology.—C. Cavenagh, J. T. Harold, E. J. K. Hogan, H. T. J. Kennedy, J. F. Sheppard, and H. E. Stone.
Passed in Midwifery.—C. Cavenagh, J. T. Harold, and H. T. J. Kennedy.
Passed in Hygiene &c.—J. J. Dolan, J. W. Griffin, and E. C. Hodgson.

THE seventy-first annual meeting of the Glasgow Eye Infirmary was held on Jan. 23rd, Sir James King, Bart., presiding. The total number of new cases during 1894 was 15 267; the in-patients amounted to 1419. A large proportion of the cases were the result of accidents in factories and mechanical works, and some arose from mishaps with bottles of aerated water. The treasurer's statement was satisfactory, the ordinary income being £300 in excess of the expenditure.

THE SANITARY INSTITUTE.—The nineteenth London course of lectures and demonstrations for sanitary officers commenced on Friday, Feb. 1st, at the Parkes Museum, Margaret-street, W. The first seven lectures deal principally with Physics and Chemistry, and serve as an introduction to the main course. Dr. R. T. Hewlett will lecture on Elementary Bacteriology on Tuesday, Feb. 12th. Among the names of those who will deliver the more advanced lectures on subjects pertaining to public health are the following: Sir Douglas Galton, Dr. Herbert Manley, Professor Wynter Blyth, Dr. J. F. J. Sykes, Dr. Arthur Newsholme, Professor Bostock Hill, Dr. Louis Parkes, Dr. Edward Seaton, Professor Corfield, and Dr. L. W. Darra Mair. Tuesdays and Fridays are appropriated to the lectures, and Wednesdays and Saturdays to demonstrations and inspections of various trades and buildings.

MANCHESTER ROYAL EYE HOSPITAL.—The annual meeting of this hospital was held on Jan. 23rd in the Lord Mayor's Parlour at the town hall, Manchester, Mr. David Bannerman presiding in the absence of the Lord Mayor. The report for 1894, which was the seventy-ninth year of the hospital, showed that the total out-patients numbered 21,575 and the in-patients 1336. The latter remained in hospital twenty-one days on an average. The medical staff considered it necessary, on account of the great increase among the out-patients, that the two hospitals—in St John-street and Oxford-street—should both be open every day at the same time, which would involve the appointment of two additional officers—a house surgeon and a dispenser. The financial position of the institution was satisfactory, the income having exceeded the expenditure by £760. A legacy of £2500 has been left to the hospital by the late Mr. Samuel Weston of Manchester.

WE have received the fifteenth annual report (1894) of the Workhouse Infirmary Nursing Association. The objects of the association are threefold: to raise the standard of public opinion on the whole question of workhouse nursing; to secure the appointment of trained ladies as matrons in all separate infirmaries; and to train and supply nurses to workhouse infirmaries in London and the provinces. H.R.H. Princess Christian is patroness and H.R.H. the Duchess of Teck is president. During 1894 the association supplied eighty-two nurses to thirty-six union infirmaries, and appointed superintendents of nurses to Plymouth Workhouse Infirmary and to Barton Regis Infirmary. At Bedford Workhouse a nurse sent by the association was dismissed by the guardians without explanation. In the result much local feeling was excited, the President of the Local Government Board was questioned in the House of Commons, and at the next parochial election all the guardians, except the two who had opposed the dismissal of the nurse, were rejected by large majorities.

THE Hospital for Infectious Diseases, newly erected by the corporation of Bangor, was on Jan. 23rd formally inaugurated by the Mayoress (Mrs. Langford Jones), who opened the door of the principal ward with a silver key and declared the building open for the reception of patients. A large company were present, including Lord and Lady Penrhyn and the Bishop of Bangor. The Mayor of Bangor (Alderman R. Langford Jones, M.R.C.S., chairman of the Sanitary Committee), in the course of an address, stated that patients would be admitted without payment.

MANCHESTER MEDICO-ETHICAL ASSOCIATION.—At the annual meeting, held on Jan. 25th, 1895, the following gentlemen were elected as office-bearers and committee for the year 1895:—President: Dr. S. Woodcock. Vice-Presidents: Dr. J. B. Brierley, Dr. C. G. L. Skinner, Dr. A. Stewart, Mr. A. W. Stocks. Treasurer: Dr. D. Lloyd Roberts. Secretaries: Dr. F. H. Collins, Mr. John Ferguson. Committee: Dr. E. V. Brown, Mr. F. J. W. Cox, Mr. Richard J. Dearden, Mr. Joseph Foster, Dr. Alfred Godson, Dr. A. Helme, Dr. James Holmes, Mr. Walter E. Husband, Dr. E. T. Milner, Dr. W. E. S. Scott, Mr. W. Thorburn, and Dr. J. Watson.

PRESENTATION.—On Tuesday, Jan. 22nd, at a banquet given to Mr. W. P. Bothamley upon the occasion of his resignation of the post of medical officer of the eighth district of the Hackney Union, a very handsome silver fruit and flower stand was presented to him by Mr. J. Owen-Perry, the clerk to the guardians, on behalf of the officers of the Hackney Union, in the presence of a large company. With reference to this presentation the clerk to the guardians writes to us as follows: "By the resignation of Mr. Bothamley the guardians have lost the services of a capable and zealous officer and the sick poor a very kind and sympathetic medical officer."

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—At a meeting of this society, held on Jan. 17th, Dr. Porter in the chair, Dr. Arthur Hall showed (1) A Case of Acute Myelitis with almost Complete Paraplegia, Analgesia, Acute Bedsores, loss of knee-jerks and plantar reflexes in a girl aged twelve years, terminating in complete recovery; (2) a case of Aneurysm of Arch of Aorta just above the root of the left lung in a woman aged forty-five years; (3) a case of Tertiary Syphilitic Eruption on the face and Periosteal Swelling of the Tibia in a young married woman with no history of syphilis; (4) a case of Tuberculous Eruption of the Skin. Dr. Porter showed a specimen of a Cystic Tumour of right Kidney which had been aspirated during life and the fluid from which contained abundant crystals of cholesterol and blood débris. From a microscopic section it appeared to be of a sarcomatous nature. Mr. Pye-Smith showed a Zwancke's Pessary encrusted with phosphates, which he had removed from a woman aged seventy-three years who had worn it continuously for over twelve years. It had ulcerated through the bladder and also through the posterior vaginal wall, but not into the rectum. It was easily removed after dividing it with a compound bone-cutting forceps, but the patient sank and died twelve days afterwards. Mr. Pye-Smith also showed a Cirrhotic Liver removed from the body of a child aged twenty-two months. There was no alcoholic history. The other viscera were healthy. The liver weighed under twelve ounces and presented a well-marked hobnail appearance. Microscopic sections confirmed the diagnosis. Dr. Wilkinson showed Hydatid Cysts of the Liver and Primary Sarcoma of the Kidney with Secondary Growth causing Fracture of the Femur. Mr. Cayley read brief notes of a case of Convulsions probably due to Poisoning by Camphor.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

THE INDEX TO THE LANCET.

THE Index for the last half-year was published in our issue of Dec. 29 h, which completed the second volume of the year 1894. Those of our subscribers who may wish to be supplied with loose copies can obtain the same (without extra charge) on making application to the Manager.

ALLEGED DETERIORATION OF CORKS.

WE have received a letter from a correspondent complaining in unqualified terms of the present cork. He finds that although willing to pay a fair price he gets a dry, brittle, worm-eaten article, too short, and the same size all the way down, "as if cut off a stick." We cannot inform him if his strictures are generally endorsed in the profession, but probably not, as no previous complaints have reached us.

G.—Our correspondent may notify to the patients of his predecessor in the practice that he has succeeded to the practice; but he must not send circulars to the patients of other medical practitioners or distribute testimonials among them.

Mr. S. Wesley Wilson.—Our correspondent's letter so clearly imputes corrupt motives that he will not be surprised that we do not print it.

"A TAPEWORM IN THE URETHRA."

To the Editors of THE LANCET.

SIRS,—The interesting note under the above heading in THE LANCET of Jan. 26th (p. 255) reminds me of a very similar case which I observed some eight years ago at Guy's Hospital. I then happened to see a segment three inches long of *Tenia solium* wriggle through the meatus urinarius of a patient who was under the care of Mr. Arthur Durham. An explanation of this very unusual occurrence was easily found in the fact that the segment of tapeworm must have found its way into the urethra through a fistulous opening which the patient possessed between the neck of the bladder and the rectum. In connexion with Dr. Axel Spoof's case no mention is made as to any communication between the alimentary and the urinary tract. Without such explanation the facts published seem to me unintelligible.

I am, Sirs, yours faithfully,

Wood Green, N., Jan. 29th, 1895.

T. SLATER JONES.

CERTIFICATION OF MIDWIVES.

A CORRESPONDENT writes to us as follows:—

"Owing to an unfortunate death of a woman in labour under the care of an uncertificated midwife the island of Guernsey authorities are about to pass an "Ordinance" requiring that every woman practising as a midwife should provide a certificate of having received the necessary education for the purpose. Will you kindly inform me where to get such information as would enable the authorities to frame a law; also where certificated midwives are to be obtained; and also whether there is a law controlling midwives in France, &c.?"

* In France midwives practise under the provisions of the Medical Law of Nov. 30th, 1892. They must be provided with a diploma issued by the Government after examination. A diploma of some sort is required by any woman practising midwifery in most of the States of Europe—e.g., Spain, Germany, Austria, Hungary, Italy, Norway, Sweden, Denmark, and Russia all impose some condition of this sort. Several States in America—e.g., Michigan, Minnesota, and New Jersey—have similar laws. A scheme of compulsory registration for midwives in the United Kingdom was formulated by a Committee of the House of Commons in 1893, and is embodied in a Parliamentary paper (No. 367) ordered by the House of Commons to be printed on Aug. 8th in that year. This paper may be obtained from Messrs. Eyre and Spottiswoode, or any other agents for the sale of Parliamentary papers.—ED. L.

Dr. Weston.—Our correspondent raises the very large question as to whether all medical officers of health ought to give their whole time to the duties of their office. One aspect of this question will be found in the next instalment of our special articles upon difficulties under the Infectious Disease (Notification) Act. The question as a whole cannot be answered yet; so many special circumstances have to be taken into consideration.

F.R.C.S.I.—The association between pleurisy with effusion and phthisis has been noticed especially by French writers, some of whom go so far as to claim a tuberculous origin for most such pleuritic cases. We shall, however, be able to receive records of the cases mentioned by our correspondent.

Medicus.—"Outlines of Practical Histology," by Professor Stirling (London, Charles Griffin and Co.).

"SULPHUR *v.* ANTITOXIN IN THE TREATMENT OF DIPHThERIA."

To the Editors of THE LANCET.

SIRS.—Mr. Hawkins Cuthbert of Aberdovey, in THE LANCET of Jan. 26th, draws attention to the use of sulphur *v.* antitoxin in the treatment of diphtheria. There is no denying the fact that sulphur is a most excellent remedy in all ulcerative throat affections, but there is as little doubt that it is not a specific for diphtheria. I have used sulphur dusting for years in diphtheria, and still use it conjoined with antitoxin. A month ago I had a case of diphtheria treated for three days with sulphur, but all the time the symptoms continued to become more grave. Antitoxin was injected, and in twenty-four hours improvement commenced and continued, the patient making a good recovery. It is impossible to say what might have happened had no antitoxin been used; but coincidences are not so common. It would be very wrong of those of us who believe in sulphur to become faddists by sticking to it in face of the evidence which has been submitted to us. It still remains a very important accessory in the treatment of diphtheria.

I am, Sirs, yours faithfully,

Hawick, Jan. 26th, 1895.

JOHN R. HAMILTON, M.D.

J. J., M.D. & J.P. (Edinburgh) is thanked for his communication. We are afraid, however, that its insertion would not be likely to answer any practical purpose, as the large majority of the department are strongly opposed to our correspondent's views in regard to the points he has put forward and advocated.

Mr. A. F. Merton.—The particulars required could only be obtained by application to the officers of the various general and special London hospitals, and would then only be given to persons proving that they desired to obtain the records for ends likely to be serviceable to medical knowledge.

Dental Pupil.—We are not aware that the articles have been republished in pamphlet form; our correspondent is advised to apply to the journal where they originally appeared.

Perplexed is bound by the bond.

"MEDICAL ELECTRICITY."

To the Editors of THE LANCET.

SIRS.—Be pleased to inform me as to the best practical book on medical electricity for the use of a general practitioner, and much oblige,
Yours faithfully,
Jan. 29th, 1895. ELECTRIC.

* The best and simplest book upon the subject is "Medical Electricity," by Dr. H. Lewis Jones and the late Dr. Steavenson.—ED. L.

MEDICAL MEN'S FEES AND THE CORK MOVEMENT.

A CORRESPONDENT of the *Irish Times*, referring to our remark that families with a joint income of £200 or over should make it a point of honour to have a private medical man and to pay him adequate fees, asks for a definition of the expression "adequate fees" and invites the Cork medical men to state what their charges are. This is not altogether an unreasonable request. Medical men are known to charge their patients according to their means, either roughly judged by their house rent or by those more refined indications of circumstance with which few are more familiar than they. It is for the men of Cork to judge how far, as a part of this controversy, it would be possible for them to commence a scale of professional charges, as has been done in other places. It would tend to correct an impression that they are higher than in other parts of the United Kingdom, and would, we feel sure, show that they are as practical in meeting the case of families with incomes over £200 a year as in meeting the case of club patients.

Inquirer.—Our correspondent's duty is to preserve the life of his patient, and to reserve professional secrets for his own use to this end. He is not called on to be the accuser of his patient, even though she be a member of the same church. The authorities of the church must act on their own responsibility and on other evidence than his. No medical man would consider it his duty to report unsuspected sin in a patient of which he was cognisant in a professional way to ecclesiastical authorities. *A fortiori* it is not his duty where other evidence is available and actually forthcoming. As a member of the church he should abstain from all action and advice, just as a member of a court who has special reasons for not discharging any judicial or witnessing function.

Rev. F. J. Muspratt.—We are obliged for our correspondent's letter; but we are sure that the practitioner eulogised therein would not care for a dissemination of his praises that is coupled with a reflection upon the skill of his medical neighbours.

"ON THE OCCURRENCE OF DIPHThERIC PARALYSIS WITHOUT PREVIOUS FAUCIAL AFFECTION."

To the Editors of THE LANCET.

SIRS.—In the letter I wrote to you for the purpose of pointing out the mistake made in the spelling of my name by Dr. Leonard G. Guthrie, and which you did me the kindness to insert, believe me when I explain that it was my ambiguous and misleading composition, and not at all my intention, that caused Dr. Guthrie to appear, instead of myself, as the one indifferent to the case. My feelings and sentiments to Dr. Guthrie are quite the opposite of this, I can assure you, and I thank you for giving me an opportunity of saying so.

I am, Sirs, yours truly,

Stockton-on-Tees, Jan. 29th, 1895.

A. ROSS PATERSON.

Mr. John Galloway.—1. We think that the first consultant sent for was entitled to two guineas.—2. We cannot see the claim of the second consultant to a fee who was not sent for either by the patient or the practitioner in attendance.—3. Our correspondent should call on the first consultant and discuss the matter in a friendly spirit. The facts seem very simple as given in his letter and should occasion no dispute.

WANTED, A LANTERN AND SLIDES.

To the Editors of THE LANCET.

SIRS.—Will any of your readers kindly inform me if a lantern with suitable slides to illustrate a popular physiological lecture could be hired at a reasonable rate? If so, of whom? The lecture is intended to embrace some of the salient points of the physiology of the whole body.

I am, Sirs, yours truly,

Jan. 28th, 1895.

Jettsonian Lectures

ON THE

COMBINATIONS OF MORBID CONDITIONS OF THE CHEST.

*Delivered at the Medical Society of London on Feb. 4th, 1895,*By FREDERICK T. ROBERTS, M.D.,
F.R.C.P. LOND.,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS AT UNIVERSITY COLLEGE; PHYSICIAN AND PROFESSOR OF CLINICAL MEDICINE AT UNIVERSITY COLLEGE HOSPITAL; CONSULTING PHYSICIAN TO THE BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

LECTURE II.

VI.—COMBINATIONS IN ACUTE CASES.

MR. PRESIDENT AND GENTLEMEN,—I now invite you to a discussion of certain aspects under which acute chest cases come before us in practice, presenting combinations of conditions which we are bound to recognise if we desire to understand these cases properly, and to treat them intelligently and rationally. I do not know whether my experience accords with that of others here present, but I meet nowadays with so many acute chest affections of a more or less complicated nature that it is really quite a comfort to come across a case that is fairly simple.

A.—Acute Conditions supervening on Chronic.

It is a very common event for some acute chest affection to supervene upon chronic morbid conditions of various kinds, and this is a most important point in relation to my subject. The natural tendency is to look upon an acute complaint as the sole mischief, especially if nothing is known about the previous history of the patient, and therefore it is always necessary to guard against this tendency, and to be constantly on the look out for any preceding chronic changes which happen to be present. On the other hand, when such changes are known to exist, and especially if they are pronounced, the development of any acute complication demands immediate recognition, as well as intelligent study in relation to the circumstances under which it occurs. I will now proceed to give a few illustrations of the more prominent combinations which have to be recognised under this category, so far as they have come within my own personal experience.

1. I must just refer once more in this connexion to the importance of always recognising the presence of certain conditions of the chest walls and other minor changes, discussed in the former lecture, when an acute affection develops in this region. That under such circumstances, especially if they are pronounced, they add more or less, and often seriously, to the troubles and dangers associated with such an affection is indisputable, and they may contribute in no small degree to a fatal result. I need scarcely say that the occurrence of an acute inflammatory disease as a complication in a case of a marked chest deformity is often most grave.

2. The importance of pleuritic adhesions in relation to acute diseases of the chest is so manifest that I make no apology for discussing this point in some little detail. In the first place, it is interesting to note that when a local adhesion exists, the history of which is quite unknown, the corresponding limitation or undue prominence of signs of a bronchial catarrh may reveal its presence and site, and I have known this happen again and again in the same case.

A far more important condition to be noted in its association with acute affections of the chest is the existence of a unilateral basic adhesion, extending more or less upwards, the signs of which may or may not have been previously evident. There is generally a history of some acute illness, be it only known by the expression "congestion of the lungs," and of course the practitioner may be aware of all the facts of the case. This condition always acts as a predisposing cause for the special implication of the lower part of the affected lung, which is embarrassed by the adhesion; and even when the patient has merely a slight cold, but still more if he has a definite bronchitic attack, the signs usually

No. 3728

become so marked and out of proportion over the corresponding base that anyone who is not aware of the combination is very likely to attach far greater importance to them than they deserve, and to diagnose a serious congestion of the lung (which in a certain sense may be correct) or an actual pneumonia which does not exist. Therefore, whenever moist râles in more or less acute cases are heard only or in marked excess over one base, other signs of pneumonia being absent, the possibility or even probability of an adherent pleura being the explanation should always be borne in mind.

There is one class of case to which I particularly wish to refer in connexion with basic pleuritic adhesion. The tendency of this condition is not only to embarrass the lung and probably to damage its structure to some degree, but also to retain secretions or any morbid products which may be formed in the bronchial tubes or air vesicles. I frequently meet with cases in which râles due to such accumulation are constantly present at one base, varying in their amount from time to time. Indeed, sometimes, in association with a general agglutination, they are heard extensively over one side, and I have ventured to give to these adventitious signs the term "adhesion râles." Now it occasionally happens in course of time that without any obvious increase in the physical signs, indicating either pneumonic consolidation or pulmonary destruction or suppuration, more or less acute general symptoms set in, much like those of phthisis, which increase in severity, until sooner or later the patient succumbs. Local symptoms may develop or increase, but not in proportion, and there is often only a small amount of muco-purulent expectoration. Sometimes signs indicating secondary progressive implication of the lung tissues in an upward direction supervene, but they do not point to anything like a cavity. No doubt many of these cases become actually tuberculous, and they would be classed as "basic phthisis," but certainly not all. At any rate, I have met with some in which experienced bacteriologists have failed to detect any tubercle bacilli in the sputum, even after repeated examination. I have a strong opinion, however, that the grave results in all these cases are really due to micro-organisms, probably of different kinds, which gain access with the inspired air into the base of the lung, where they find a suitable nidus in the retained secretions and morbid products, in which they flourish and multiply, producing toxins which are absorbed and by degrees poison the patient. Whatever may be the explanation, the practical lesson is that a basic adhesion accompanied with the persistent presence of râles is a condition never to be overlooked or underrated, and one that decidedly predisposes to acute changes, which may be of a grave nature.

I now wish to say a few words with regard to acute conditions occurring in cases where one lung is universally adherent. Should a well-marked attack of bronchitis develop under such circumstances the signs on the two sides are likely to be quite different, and the embarrassed lung will probably suffer much more seriously than the opposite one. The relation of a generally adherent lung to acute tuberculous changes is extremely interesting and important. Unquestionably an acute phthisis with rapid destructive changes may develop in connexion with a lung which has been known to be generally adherent for a long period, but which until that time has given no apparent trouble, or it may start on the healthy side. Another tuberculous process which may possibly complicate a general chronic pleuritic adhesion is what may be described as an outburst of military tuberculosis in the corresponding lung, while the opposite one is practically free.

Before leaving the pleura I may mention that sometimes an acute intra-thoracic inflammation complicates the pronounced combined conditions associated with this structure alluded to in the previous lecture. The possibility of such a complication in a case of empyema which has communicated with the lung must also be noted, of which I have met with more than one striking instance.

3. With regard to the more definite chronic diseases of the chest, it must be borne in mind that acute complications may occur in connexion with any pulmonary affection, cardiac diseases, aneurysm, &c., or in more or less complex cases. The supervention of an acute complication upon a chronic cardiac affection is always a serious matter, and demands the most careful attention. Of course, any acute inflammatory disease associated with the respiratory organs may set in, and its dangers are likely to be much increased under the circumstances. Certain forms and combinations of cardiac diseases are liable to produce at any time acute pulmonary

congestion with oedema, or sometimes embolism and infarction; or hydrothorax may occur. The development of an acute endocarditis, probably malignant, on an old valvular disease is of supreme consequence, and this possibility should never be forgotten. When this condition happens to be added to an already complicated heart case, with an adherent pericardium, possibly accompanied with extensive aortic degeneration, the entire combination is from all points of view extremely grave.

B.—Associated Conditions in Air Tubes and Lungs.

It is important to draw attention to the fact that in a considerable proportion of cases in which the lungs are acutely affected, we have to deal with a more or less complicated state of things, as regards the actual conditions in these organs and in the air tubes. For instance, a mere attack of bronchitis, by obstructing the tubes in different degrees, leads, on the one hand, to temporary accumulation of air and consequent pulmonary distension, or, on the other hand, to pulmonary collapse of lobular or more extensive distribution. The expression "congestion of the lungs" is commonly employed in relation to acute chest cases in the most vague way possible, and is in not a few instances absolutely wrong and misleading; nevertheless, I wish to point out particularly that this is a real condition, which frequently forms an important element in a case, either directly or by its effects. Thus, in connexion with croupous pneumonia, especially if of rapid onset and extensive, or if both lungs are involved, the disturbance of the pulmonary circulation is sure to lead to congestion of more or less of those portions of the organs which are not consolidated, and it may be of practical consequence to recognise the combination. The conditions termed "broncho-pneumonia" and "capillary bronchitis" are also in reality of a mixed character, in which pulmonary congestion takes a prominent part. It is likewise associated with acute miliary tuberculosis, giving rise to certain of the signs observed in this disease.

C.—Secondary Effects of an Acute Disease.

Important combinations of morbid conditions come under this head, but it must suffice to give two or three of the more prominent illustrations. Cases of acute inflammatory effusion in the pleura or pericardium, or both, afford some of the most striking examples we have of the secondary effects of physical conditions within the chest, referred to in the previous lecture, and the combinations resulting therefrom are often very grave, not only in themselves, but also owing to the rapidity with which they are produced. Dropsy of these serous cavities developing acutely would give rise to similar consequences. Again, acute pulmonary affections not uncommonly act seriously upon the heart in different ways. Thus, an attack of bronchitis in a case of pronounced chronic emphysema tends to greatly embarrass the right heart, causing accumulation of blood in its cavities, actual temporary dilatation, or possibly cardiac thrombosis. Similar consequences are observed in cases of rapid and extensive broncho-pneumonia or capillary bronchitis, even when the lungs have been previously perfectly healthy, and the cardiac complications add seriously to the danger of such cases. In a severe case of croupous pneumonia, not only may similar difficulties arise, but the myocardium is also liable to undergo serious acute degenerative changes. On the other hand, secondary lesions in the lungs are likely to follow certain acute conditions associated with the right heart—namely, clotting of blood in its cavities, and endocarditis, especially if of the malignant variety.

D.—Combinations of Acute Inflammatory Diseases.

I now approach a question of great interest and practical moment in relation to acute diseases of the chest, and that is the various ways in which the several inflammatory diseases may be combined in particular cases. I am convinced that the frequency with which such combinations occur in actual practice is not by any means realised as it ought to be. It is impossible to do more in this lecture than to offer a few general remarks on this part of my subject.

1. *Tracheo-bronchitis.* Varieties of bronchitis.—I merely mention tracheo-bronchitis in order to point out that inflammation of the trachea is in many instances a very prominent element in acute bronchitic cases—at any rate, at their commencement—and, as a matter of fact, is mainly accountable for the early symptoms. It is further worthy of note that the term "bronchitis" really includes conditions

of different kinds, which are frequently associated in the same case.

2. *Pleuro-pneumonia.*—This is another expression in common use to which no very clear or definite meaning is attached. A certain amount of pleuritic exudation may be regarded as an almost essential concomitant of a pneumonia reaching the surface of the lung. There is, however, quite another class of cases, though I believe some authorities dispute their reality, in which pleuritic effusion and pneumonic consolidation exist together, sometimes developing more or less simultaneously, but more frequently one condition following the other. Then there are the cases in which, on the one hand, an acute empyema opens into the lung; or, on the other hand, a pulmonary abscess resulting from pneumonia bursts into the pleural sac; moreover, in cases of pulmonary abscess pleurisy may certainly be set up without any actual communication with the cavity of the pleura.

3. *Broncho-pneumonia.*—This may be regarded as a combination of acute inflammatory affections of the respiratory organs, but it needs no more than a passing mention. The association with this disease of non-inflammatory conditions involving the lungs has already been referred to.

4. *Bronchitis with lobar pneumonia.*—A certain degree of bronchitis is often associated with lobar pneumonia, but I draw attention to this class of cases more especially in order to emphasise the fact that a patient may have an extensive bronchitis, with abundant purulent or muco-purulent expectoration, while the lower lobe of one lung is at the same time the seat of definite lobar pneumonia. Under the circumstances the pneumonic consolidation is decidedly in danger of being overlooked, as I have known happen more than once.

5. *Diphtheritic extension.*—It will be convenient in this connexion briefly to notice those cases in which diphtheritic membrane spreads down the air passages into the bronchi, finally extending more or less into their smaller ramifications. This is of course a form of inflammation, while it gives rise to other inflammatory conditions, as well as to secondary pulmonary changes, which ultimately frequently lead to a very complicated state of things.

6. *Pericardial and cardiac inflammations.*—A very important class of acute cases which come under the category we are now discussing, are those in which pericarditis is associated with endocarditis, or there may even be at the same time a myocarditis. They are by no means uncommon, more especially in connexion with rheumatism in young subjects, and we see the results of the combination in many chronic cardiac cases which come before us in later life. The late Dr. Sturges, whose unexpected death under such sad and distressing circumstances we have to deplore, discussed this aspect of the subject in a very interesting and instructive manner in his Lumleian Lectures for 1894, and I cannot do better than refer you to these lectures for further details.

7. *Complicated cases.*—Lastly, we now and then meet with cases of acute intra-thoracic inflammation which can only be described as "complicated." Exceptionally these cases present an extremely intricate and complex aspect, especially if there happen to have been previous chronic conditions. Thus there may be more or less pleuro-pneumonia on both sides; double empyema; pericarditis may supervene on a pneumonia or pleuro-pneumonia; or there may even be a complication of pleurisy and pneumonia, perhaps double, with pericarditis, endocarditis, myocarditis, and a mediastinitis thrown in. The class of cases last mentioned may be associated with acute rheumatism, when, though very grave, they are not necessarily fatal; with influenza; or with some obvious internal septic or pyæmic condition. The direct causative relation of micro-organisms to all acute intra-thoracic inflammatory diseases is at the present time a favourite doctrine; and, at any rate, they are certainly concerned in some of these cases.

E.—Tuberculo-inflammatory Conditions.

There is a special class of cases which I think may be fairly differentiated under this heading. They come before us in different aspects: it may be as an ordinary lobar or more limited pneumonia, not necessarily apical; more commonly as a disseminated lobular or patchy pneumonia; or in some instances as a marked pleuritic or pleuro-pneumonic case. The foundation of all these lesions, however, is tubercle, as the course of events as a rule soon declares. Patients with these conditions may be actually walking about, and come to the hospital or consulting room for advice, the early symptoms not having been

sufficiently pronounced to attract much attention. I have known such cases present themselves for the first time with a temperature of 103° F. or more and obviously seriously ill. Sometimes the lesions follow a more or less profuse unexpected hæmoptysis. There is no class of acute cases against which we need to be more constantly on our guard, lest we should fail to detect them or misinterpret their significance. They do not necessarily go steadily from bad to worse, for the inflammatory products not uncommonly to a great extent become absorbed, the patient improving in a corresponding degree. The definite phthisical changes, however, usually remain, and the ultimate issue is sooner or later as a rule but too inevitable. Exceptionally, under favourable conditions of home treatment, climate, &c., cases of this kind undoubtedly practically recover; on the other hand, their history is far more likely to be that of a very acute phthisis.

F.—Miscellaneous Conditions.

I have thus designated a separate group of cases in order to indicate the fact that the organs contained within the chest, which are so essential to life, are liable to be affected in an acute manner, and to present more or less serious combinations of conditions, under circumstances which do not fall under any of the preceding classes, but which, nevertheless, it is highly important that we should recognise. I refer, for example, to those which result from, or are associated with, poisonous inhalations, not forgetting fogs; toxic causes; the "typhoid state"; exposure to extreme cold; partial suffocation; and certain nervous diseases. Their effects are evidenced by more or less grave disorders of the respiratory and circulatory functions; and it will suffice to state that they may more immediately give rise to such conditions as pulmonary congestion and its consequences, especially hypostatic; coagulation of blood in the vessels; embolism and infarction; pulmonary paralysis; cardiac dilatation or thrombosis; or failure of the respiratory muscles, especially the diaphragm. Inflammatory complication may of course subsequently supervene.

VII.—ACCIDENTAL LESIONS OR COMPLICATIONS.

Under this head I propose to notice very briefly certain classes of cases in which, usually quite suddenly or at any rate very acutely, some definite event or lesion occurs within the chest, which is associated with, and is the direct result of, some previously existing morbid condition or conditions. As a rule the complication is indicated by phenomena of a pronounced and often grave character; and it may cause immediate or very speedy death.

The important sudden lesions, not immediately fatal, which we have to be prepared for in practice as possible complications of previous diseases, are pneumothorax; the bursting of an abscess or collection of pus, especially of an empyema into the lung, a pulmonary abscess into the pleura, or a mediastinal abscess in different directions; some lesion leading to mediastinal and subcutaneous emphysema; rapid and extensive cardiac or pulmonary thrombosis; rupture of a cardiac valve or septum; certain forms of hæmorrhage, with grave hæmoptysis; changes affecting an aneurysm, especially its rapid enlargement or extension in certain directions, or its communication with the superior vena cava; and rupture of an oesophageal pouch, which, however, is an extremely rare event.

Pneumothorax is, of course, in the large majority of cases a complication of phthisis, but the possibility of its occurrence in this disease is not always appreciated as it ought to be, and I have known the lesion utterly mystify a clinical observer even when all the evidences of the condition were perfectly pathognomonic. It must be remembered, moreover, that pneumothorax may be on a limited scale, owing to the existence of pleural adhesions, and then it may not give rise to any serious disturbance in the way of symptoms, though the physical signs may be characteristic enough. Cardiac thrombosis and its consequences demand very careful study, and may be exceedingly difficult to recognise or understand. Hæmoptysis is usually regarded as a symptom, but when severe it is really an evidence of some definite lesion, the nature of which is generally clear enough, in relation to the known circumstances of the case, but certainly not always. Its occurrence is from this point of view of great significance in certain cases of phthisis, as well as in relation to the bursting of an aneurysm into the air passage.

One of the most interesting lesions which may occur in

connexion with an intra-thoracic aneurysm is the sudden formation of a communication between it and the superior vena cava, of which the following case is an interesting example. Some years ago I had under my care a very obscure and complicated case of aneurysm of the arch of the aorta. When I first saw the patient he was in great distress on account of his breathing, and, by the way, was supposed to be suffering from asthma. He improved so much under treatment that he became rather lax in carrying out instructions, and after a day of sight-seeing he was during the night suddenly seized with very grave symptoms. A neighbouring practitioner was summoned, and the sight that met him was that of a man suffering from urgent dyspnoea and struggling for his life, at the same time presenting a swollen and intensely cyanotic aspect. The patient was conscious that something had gone wrong in his chest, and drew the attention of the medical man to a tremendous thrill and a whirring noise which could even be heard at a distance. Need I say that he was somewhat taken aback, and could not quite understand the state of affairs. I saw the patient some hours afterwards, and he was so changed that I could not have recognised him. The physical signs persisted, and all the phenomena of obstruction of the superior vena cava became extreme, but the patient lived for some weeks.

VIII.—SUDDEN OR ACUTE DISORDERS OF FUNCTION, TEMPORARY OR PAROXYSMAL.

Under this head I have to draw attention to another most important group of combinations, in which sudden or acute disorders occur, sometimes very grave, which are often spoken of as functional, and which at any rate cannot be attributed directly to any definite structural lesion or change. The conditions to which I chiefly refer in this connexion are: 1. Respiratory disturbances, especially attacks of so-called "bronchial or spasmodic asthma"; cardiac dyspnoea and certain other forms of disturbed or excessive breathing; disorders associated with the larynx, due to interference with intra-thoracic nerves; and certain diaphragmatic functional difficulties. 2. Cardio-vascular, including mainly excessive or disturbed cardiac movements of various kinds, and palpitation; weakness or failure of the cardiac action, with syncope; and the complaint known as "angina pectoris." 3. Dysphagia, due to some functional disorder of the oesophagus. I may also note here that we should always take into consideration in cases of acute inflammatory diseases of the chest the important influence of the nervous system upon the respiratory and cardiac functions, by which the symptoms may be materially modified; and in all cases to be prepared for the possible tendency to what I may call "neurotic exaggeration."

Such terms as "asthma" and "angina pectoris" are unquestionably often thought to represent entirely independent complaints, at any rate by the laity, and we cannot too strongly insist upon the fact that they are not so in a large majority of cases, but that various structural changes, usually quite obvious, determine the occurrence of an attack. Some of the disorders alluded to may, like grave and sudden organic lesions, kill instantly or very rapidly, as when death happens from cardiac failure supervening on heart disease, or from angina pectoris; otherwise the attacks are of a temporary nature, and certain of them tend to be paroxysmal.

"Asthma" is a term of decidedly indefinite application, and it is not infrequently applied to cases which are really not asthmatic at all, while much more grave conditions, such as certain disturbances produced by an aneurysm, may be mistaken for this complaint even by experienced observers. The attack or "fit" of asthma, however, as a rule presents very characteristic features. In the large majority of instances it supervenes upon distinct and obvious morbid changes associated with the chest, which tend to become more and more pronounced as the case progresses. The cases in which asthma occurs are, as is well known, usually more or less of the "emphysematous and bronchitic" type, but rigidity of the chest walls, adhesion of the upper part of the lung, and other factors which I have already discussed are often of much importance in these cases in relation to asthmatic attacks. Another point to be remembered is that chronic cardiac disease may be present, and also that the right cavities of the heart become more or less overloaded with blood during the paroxysm. These complications when present must be adequately taken into account in relation to the symptoms observed in an asthmatic case.

Angina pectoris is another affection associated with the

chest which usually complicates more or less definite morbid conditions of an organic nature, and whatever view we may hold as to its pathology, it is obviously essential in each case to try to determine what the particular changes happen to be. Those which are most likely to be overlooked are atheroma or calcification of the aorta and coronary arteries, and cardiac degeneration not of a pronounced character.

IX.—MORBID CONDITIONS ORIGINATING FROM THE ABDOMEN.

It may seem needless to burden a subject already sufficiently complicated by dragging in the abdomen in relation to the chest, but this aspect of it must not be forgotten, though I will only allude to two or three points. It is not at all uncommon for accumulations of various kinds within the abdominal cavity so to interfere with the diaphragm and the thoracic contents as to lead to a very decided combination of morbid conditions, which may demand active interference for their relief. The trouble is all the greater if there happen to be previous organic diseases within the thorax. Extreme tympanites, ascites, any large abdominal tumour, and pregnancy afford familiar illustrations of the conditions originating these difficulties. The association of pregnancy with serious pulmonary or cardiac diseases, or both, often presents a very trying problem, both as regards diagnosis and treatment, especially if some acute chest affection still further complicates matters, a combination of which I have met with some striking examples. Again, an enlarged spleen or liver, or a renal tumour may encroach in various degrees in an upward direction, so as to lead to more or less obvious or serious consequences. The rupture of an abdominal abscess, not forgetting sub-phrenic, or of a hydatid cyst into the thorax, originates an important class of cases. I will only add, further, that to be called in and expected to give an immediate and positive opinion, from one examination, as to the origin and progress of a chest case which has started from some abdominal trouble, and which has existed, perhaps, for many weeks, and as to the existing state of things, with their treatment, is about the most trying experience and ordeal that any physician or surgeon, however skilled he may be, may be called upon to undergo.

CLINICAL LESSONS: INVESTIGATION OF CHEST CASES.

Having thus attempted to give some comprehensive summary of the chief combinations of morbid conditions of the chest, I now proceed to look at my subject from another point of view, with the intention of trying to bring out certain practical clinical lessons which I think it is calculated to teach, and of offering some general remarks on the investigation of chest cases. I take it for granted to start with that the advantages of some systematic arrangement of this kind for clinical purposes will be acknowledged by all who have had much experience in such cases. Personally I have found it of the greatest help, and I have no hesitation in affirming that without a fairly clear comprehension of, at any rate, the more common chest combinations which are likely to be met with, it is impossible to undertake the investigation of individual thoracic cases with any degree of confidence.

1. My first proposition, which needs to be emphatically urged in these days of hurry and bustle, is that every thoracic case is worthy of at least a fair amount of study and consideration, and that it is our duty to try to determine as accurately as possible what are the actual conditions which in various combinations we have to take into account. A chest case would, I suppose, be ordinarily understood to signify one in which symptoms of some kind and degree attract notice to this region. If these should happen to be of a pronounced character, be they sudden, acute, or chronic, no doubt they would receive as a rule adequate consideration; and it may be observed in passing how often serious combined morbid changes are thus brought to light by some accidental event, or, it may be, by what looks like a mere passing functional disorder. Should they, however, be slight or indefinite, then comes the special danger of superficialness or actual neglect of investigation. Over and over again have I found some apparently trivial symptoms to be the earliest revelation of various associated changes, not uncommonly of a pronounced and serious nature, of which it may be of the highest importance to the patient to be fully aware, if only from a preventive point of view.

2. The next point which I wish to enforce is that every chest case should be approached with an open, I may say a "comprehensive," mind and an unbiased judgment, both

as regards structures and diseases. At any rate, it is most dangerous to have a too definite or preconceived idea as to this or that organ being affected, the supposed nature of the complaint as expressed in a name, and the conditions which we expect to find. We must always be prepared, moreover, to meet with combinations of morbid conditions, affecting several structures it may be, for which we were entirely unprepared, even in cases which are apparently clear and simple; and sometimes we are confronted with such a complex or curious state of things that only a clinical observer fully acquainted with the particulars I have indicated is likely to understand it in the least. In dealing with sudden or acute cases we have to be specially on our guard against a too narrow conception of their nature and combinations, otherwise we shall be ever in danger of making most grave and irreparable blunders; but even in chronic and ordinary cases the same principle must guide us as a general rule, if we wish to avoid serious errors in diagnosis.

3. I now proceed to look at the clinical investigation of chest cases from the more positive point of view in its bearings upon my subject. I suppose we are all agreed that we ought to avail ourselves of every means which we can employ in such investigation, and to study intelligently all the clinical signs which are thus presented for our interpretation in any individual instance. We must be especially careful in these days of progressive and aggressive science not to neglect the old methods which have served us in such good stead in the past, and without which we absolutely cannot get on, or to allow them to be entirely supplanted by others of recent introduction, which, after all, can only afford a limited kind of information, and some of which are by no means always reliable or easy of application. Taking a comprehensive view of the immediate investigation of a patient supposed to be suffering from some chest affection, the process may be summed up as including: (1) systematic physical examination of the thorax and its contents, by the more simple methods commonly recognised under this expression; (2) intelligent inquiry as to the presence or absence of symptoms—subjective and objective, local, general, and remote—so far as they are directly associated with and the result of thoracic conditions, and the methodical study of any such phenomena which happen to be present; and (3) the employment in appropriate cases of special methods, and amongst these would come the use of the different instruments and other apparatus which are available for clinical purposes in relation to the thoracic structures.

I desire to offer a few practical remarks with regard to each of these divisions, in their relation to the investigation of combined morbid conditions associated with the chest.

I have placed physical examination first for the following reasons. It is, in the first place, obviously the only means by which we can gain any reliable information whatever as to the presence and nature of the combinations of morbid changes affecting the chest and its contents of which I have been speaking; and, therefore, it constitutes the most advantageous starting point of our clinical investigation in a large number of instances. Secondly, it is very important to remember that combinations of thoracic morbid conditions are not uncommonly detected by physical examination which are not revealed by any symptoms whatever, or, at any rate, none of sufficient moment to attract attention. Therefore, it is a safe rule thus to investigate the chest more or less in every case which comes under our professional observation. I believe it would be a very good plan, especially under particular circumstances, if individuals would present themselves for examination from time to time, just to see what is the condition of their important organs. Now and then, but only exceptionally, one does come across a wise person who thinks it worth his while and money to be thus overhauled; and on the whole these are about the most satisfactory cases to be met with in practice. The only opportunity, however, one usually gets of investigating from this aspect is in relation to life insurance, when we do sometimes discover very remarkable and unexpected morbid changes. Thirdly, physical examination often reveals readily and positively pronounced organic conditions in various combinations, which at once explain all the clinical phenomena observed, making the case perfectly clear and simple; and amongst these conditions it may detect one which demands immediate treatment. There is one point that I wish specially to notice in this connexion. It is often stated that certain conditions within the chest cannot be detected by physical examination with any certainty, or, at any rate, only exceptionally. I

more especially allude to pleuritic and pericardial adhesions. Such a statement I strenuously dispute, and I maintain that these changes, as well as others more or less obscure, may frequently be demonstrated as parts of a case, if they are duly borne in mind and properly looked for, and if their signs are intelligently appreciated.

In the next place I desire to say a few words as to the general principles upon which physical examination of the chest should be conducted, in order to be of any real service in demonstrating the presence and nature of the various combined conditions. Concisely stated, it must be always systematic, and as thorough and comprehensive in all respects as the circumstances of the case permit, with due regard to the state of the patient. An unmethodical examination, or one limited to the upper part of the chest and perhaps the cardiac region, is by no means adequate in any case, and such a mode of procedure habitually adopted is certain to lead to many disastrous results. There is one tendency against which it is necessary to warn in this connexion, and that is the practice of always looking for some special condition, such as lung consolidation, a pleural effusion, or disease of a cardiac orifice or valve; and, should either of these be found, fixing upon it and ignoring everything else. Of course, it is essential to be thoroughly familiar with the signs of such simple conditions and to be able to recognise them positively, but we must never forget that in a large number of cases they are mixed up in every conceivable way. Of course, in every case the heart and great vessels ought to be invariably separately and systematically examined. Moreover, should any exceptional disease be suspected or discovered, such as an aneurysm or solid tumour, it is well to have a definite and special plan of examination which can be methodically carried out in such cases. While it should be the rule in relation to physical examination of the chest to aim at finding out all the conditions present in a particular case, on the other hand much discretion is required not uncommonly in carrying it out, as in cases of an acute and complicated nature, or where sudden grave lesions or disorders supervene on chronic diseases, or in advanced phthisical or cardiac cases. Under such circumstances our investigation should be as brief and as little disturbing to the patient as possible, even though we are not able to make out to our satisfaction the exact state of things, and in some instances we had far better omit physical examination altogether in the meanwhile. It is remarkable, however, what we may find out even then without disturbing the patient to any appreciable degree, if we go about the examination in the right way, and make good use of our eyes and hands. The more simple methods of examination just alluded to—namely, inspection and palpation—are also often of the greatest service in the detection of certain associated physical conditions of the chest, especially when employed together and for definite purposes, and I do not think that they are at all utilised to the extent that they might be. There is one other point that is worth noting—namely, the essential value of certain special signs in the detection of a particular and unusual condition which happens to form part of a more or less complex case. Thus, the "bell sound" or the "succussion splash" may be the only evidence under such circumstances of the pleural conditions with which these signs are severally associated.

CHRONIC GASTRIC ULCER AND ITS TREATMENT BY PAPAIN.

By GUTHRIE RANKIN, M.D. GLASG., F.R.C.P. EDIN.,
PHYSICIAN TO THE WARWICK SCHOOL.

THE symptoms produced by gastric ulcer are so well known as to need no recapitulation, and in a well-marked and recent case are so unequivocal as to make the diagnosis both easy and certain; but in the chronic form of the disorder it often happens that the symptoms are indefinite, and it then becomes a matter of difficulty to arrive at a satisfactory conclusion as to what exactly are the local pathological conditions to which the signs presented by any given case are due. Ordinary ulceration of the mucous membrane of the stomach may be produced by various causes, but one of the most frequent etiological antecedents, especially in females, is anæmia, and when anæmia is not an antecedent condition it is generally in chronic cases a consequential

one, so that it may be looked upon as a concomitant of the disease. Treatment is often unsatisfactory and the following method is submitted, not because it embraces anything new, but merely because it seems to have been productive of good results in the cases here enumerated, as well as in many others of a more indefinite character which have come under observation but which the scope of this paper will not embrace. The value of papain in gastric conditions, presumably of an ulcerative character, was first suggested to me by the following case.

CASE 1.—A woman thirty-two years of age, thin, pallid, and badly nourished.

Symptoms and history.—She experienced pain soon after eating, and she had observed that the amount of pain had been proportionate to the roughness and solidity of the food which she had taken. The pain had always been accompanied by flatulent distension, and was increased by pressure over the epigastrium. There had been a continual sense of oppression and nausea, which was relieved if vomiting occurred. Heartburn had been a distressing symptom. Her appetite had been fairly good, but could not be indulged from fear of the subsequent discomfort. Constipation had been a constant trouble. The menstrual discharge had been irregular, scanty, and pale in colour. She had had occasional palpitation, uncomfortable attacks of faintness, and breathlessness on exertion. There was extreme tenderness to touch in the epigastrium, limited to a spot on the right of the ensiform cartilage. Her tongue was clean, red, glossy-looking, and abnormally sensitive. Her pulse was small and rapid, but the cardiac dulness was normal, and the sounds were masked by a hæmic murmur. Bruit de diable was well heard in her neck. The other organs were apparently healthy, and the urine was normal. There was some distension of the abdomen, which was tympanitic on percussion all over. When a girl she suffered from bloodlessness, for which she was repeatedly under treatment for months at a time. Six years ago she had a serious illness, the leading feature of which was a large vomiting of blood, followed by a smaller attack some weeks later. She was then ill for several months, but eventually recovered. Ever since she had suffered from dyspepsia, which had become aggravated within the last three months and complicated latterly by frequent sickness. The breathlessness on exertion was a comparatively recent development.

Treatment and result.—Careful dieting and the usual succession of remedies for the relief of her symptoms brought about in time a general improvement of her health, and particularly a marked diminution of her anæmia, but there still remained pain after food, especially if solid, and periodic attacks of violent sickness. An alkaline mixture, containing papain, morphia, and strychnine, was then ordered, and under its influence the dyspeptic symptoms yielded, and she gradually experienced greater comfort than she had known for years. Suddenly one day, after unusually heavy household work which her feeling of improvement had tempted her to undertake, she complained of acute pain in her abdomen, became collapsed, and at the end of a few hours died.

Necropsy.—There was no evidence of organic disease except in her stomach, which was found at one part of its lesser curvature to be glued to the edge of the left lobe of her liver. On the mucous surface, at a point corresponding to the seat of this adhesion, there was an old cicatrix, circular in shape and about the size of a florin, but at its outer and lower edge there was an elliptical portion of fresh ulceration, and in this situation the perforation had occurred. Close by were two smaller abrasions of surface, evidently of recent date—one circular and the other oval in shape. Both were in process of healing, and the larger of the two, though still of a deeper tint than the surrounding mucous membrane, was partially cicatrised. All the abrasions were on the anterior surface of the lesser curvature. These post-mortem appearances, when viewed in the light of the history of the case and when taken in conjunction with the positive assurance of the patient that from the date of the commencement of her illness she had never been so well and free from pain as since she commenced to take the papain mixture, suggested that possibly this drug, which had not been previously administered to her, had done something towards healing the ulcerated patches, and had, as a consequence, afforded relief to her symptoms. The perforation in all probability was caused by the unusual exertion which she was unwisely tempted to undertake, and was determined at the spot where it occurred by recent activity of the ulcerative process.

at the edge of the old cicatrix, and by special tenacity of the stomach wall at that particular situation.

Acting on this supposition, papain was administered in many suitable cases, and the following are selected because they most strongly illustrate the beneficial effect of the treatment adopted.

CASE 2.—A young woman twenty-eight years of age, tall, thin, but fairly well nourished.

Symptoms and history.—For nearly a year she had had discomfort immediately after food, and during the past three weeks the discomfort had increased till it had become sometimes pain of the most agonising description. For days past the pain had been so severe and continuous that she had been afraid to swallow anything. Till lately she had only suffered from sickness very occasionally, but since the pain had become worse it had been invariably accompanied by nausea, often leading to retching, and sometimes to active vomiting. On the least exertion she became giddy and faint, and experienced a sense of pulsation all through her body. She had an almost irresistible craving for stimulants. Her catamenia had ceased entirely for six months. On her return from a short walk, the latter part of which was hurried to avoid a shower of rain, she was suddenly seized with alarming hæmorrhage from the stomach, the quantity of blood vomited amounting to about two pints. The shock of this large bleeding was great, and when first seen her condition of collapse was so extreme as to make her recovery doubtful. Hypodermic injection of ether and ergotin, together with an enema of meat-juice and brandy, however, fortunately restored her. An ice-bag was intermittently applied to the abdomen, and for six days she was fed entirely by nutrient enemata. Three days after her first attack there was a renewal of the hæmatemesis to a much smaller extent, but still enough to induce a minor degree of collapse and to necessitate the repetition of ether and ergotin hypodermically. During these six days she was allowed to suck ice *ad libitum*; a succession of two small fly-blisters was applied to the epigastrium; and creasote for two days, followed by nitrate of silver for five days, was administered internally in pill form. At the end of a week the more acute symptoms had subsided, but she was still prostrate, blanched, and with a very rapid and soft pulse. There was excessive tenderness at the pit of the stomach and the least pressure excited acute pain and produced faintness. The tongue was red, raw, and dry, causing her difficulty in articulation. Her heart sounds were muffled, but the action was so rapid as to make it impossible to be sure whether or not there was a bruit; the percussion dulness was not increased. There was no evidence of organic disease otherwise. She had been dyspeptic all her life, and at eighteen years of age she had had a similar illness to this one, but the amount of blood then vomited was comparatively small. On several occasions she had been laid aside on account of depressed health, but she did not think she had ever suffered from acute disease. She had been led to understand that she had an anæmic tendency, and she had been frequently treated for a period of weeks with iron. Her menstruation had always been irregular and for the most part scanty. There was a dipsomaniac taint in her family history, which otherwise was satisfactory.

Treatment and result.—On the seventh day of her illness she was allowed to sip milk and barley water, and the nutrient enemata were reduced to two a day. On account of a slight return of the nausea the creasote was resumed night and morning, and three times a day a pill containing papain, reduced iron, and cannabis indica was administered. Her rectum was washed out with a simple enema every morning. After three more days the creasote and nutrient enemata were discontinued, and the diet was supplemented by farinaceous puddings, light broths, &c., leading on gradually to fish, white meats, and cooked vegetables, until eventually an ordinary diet of mixed animal and vegetable substances was tried. The papain and iron pills were increased to four a day, and when she began to take solid food she was ordered in addition a further quantity of papain with her midday meal. At the end of seven weeks from the date of her first hæmorrhage she was quite well and was able to take ordinary food without discomfort. She could walk some distance, sleep soundly, and was ready and anxious to return to work. Since that illness she has three times been threatened with a return of her old symptoms; but when the pain after food has warned her that she was falling off, she has taken similar pills plus a small addition of arsenic, has restricted her diet to milk and soup,

and on each occasion she has been well within a week or ten days. For upwards of two years now she has been in vigorous health.

CASE 3.—A young woman twenty-two years of age, thin, anæmic, and delicate-looking.

Symptoms and history.—Ten days previously it came to the knowledge of her mistress that this girl was taking little or no food, and on inquiry it was found that she had been ailing for several weeks and that her refusal of food was due to the pain which it caused her. From a slight beginning this pain had latterly become unbearably acute, and, no matter what she put into her stomach, it was invariably followed in about a quarter of an hour by pain, which often quite doubled her up and which was relieved by the attack of vomiting which generally followed. Her appetite was voracious, but she dare not gratify it. She had suffered for about six months from menorrhagia. She had constant headache, was easily fatigued, and in the evening had slight oedema of her ankles. She had always had constipation. Immediately after swallowing a cup of hot tea one morning she was seized with a feeling of faintness, and shortly afterwards vomited about a pint of blood. When first seen she was recovering consciousness, her pulse was feeble and frequent, her skin was bathed in a cold, clammy perspiration, her lips were colourless, and her respiration was shallow and sighing. A hypodermic injection of ether was administered and was speedily efficacious in reviving her. Later in the day, the girl's general condition having improved, it was found that she had tenderness over her epigastrium, which increased to acute pain on pressure. There was very considerable distension of the stomach. The tongue was clean, but shrunken and pallid. The colon was loaded, the bowels not having been relieved for several days. The heart sounds were clear, but there was a hæmic murmur to be heard all over the cardiac area. The urine contained a faint haze of albumen. She had never been a robust girl, but had not suffered previously from acute illness. She had been subject at times to a troublesome cough, but it had always yielded to proper care and management. Her family history was strongly tainted with pulmonary phthisis. One sister died suddenly after a long illness from "bleeding," but whether the hæmorrhage was from the lungs or stomach it was difficult to determine, though several circumstances made it seem likely that its seat was the stomach and that death was due to perforation.

Treatment and result.—Four days after the occurrence of the hæmatemesis the combination of papain, iron, and cannabis indica was ordered. Her diet was carefully restricted, and no solid food was allowed for a fortnight. At the end of three weeks iron, quinine, and arsenic were substituted for the former combination, and papain dissolved in glycerine was given with each meal. The food was gradually added to until a full dietary was reached, and the bowels were easily regulated by enemata of turpentine and oil during the first week and thereafter by a morning dose of infusion of senna pods. In six weeks she was convalescent; her digestion was restored, her strength re-established, and she was sent to a seaside convalescent home, from which she returned after three weeks the picture of good health.

CASE 4.—A married woman forty-two years of age, the mother of five children.

Symptoms and history.—For six weeks she had suffered from loss of appetite, heartburn, constipation, flatulent distension, and pain in the stomach, more or less acute, immediately after food. These symptoms had been augmented during the past week by the occurrence of sickness, and on two occasions by distressing and prolonged retching. She had been listless, depressed in spirits, unfit for exertion, sleepless at nights, and she had been rapidly losing weight. She had a muddy complexion and her expression was anxious and worn. There was not much tenderness in the stomach region except at one spot, so small as to be covered by the tips of two fingers, immediately to the right of the ensiform cartilage, but in this situation there was great sensitiveness, and she cried out on the least pressure. So tender had it been for some days that she had been obliged to leave off her corsets. Her heart was healthy, but there was some muffling of the first sound, which became much more pronounced after slight exertion. Her tongue was coated, dry, and tremulous. Her urine was normal, and there was no other evidence of organic disease. She had once suffered from pneumonia, and all her life she had been easily upset by extra work or worry. Her menstrual function was late in being established, and for the past six months it had been in abeyance. She had always been obliged to be careful as

to her dietary, but she had never before suffered such pain after taking food. Her confinements had been normal, but on each occasion her recovery had been protracted, and she had only been able to nurse two of her children for a period of about three months each. Her family history was unimportant, but was distinctly neurotic.

Treatment and result.—A small dose of calomel was ordered for three consecutive nights, to be followed by a saline draught in the morning. Her diet was restricted to milk and thin clear soups for a week, and a mixture of bismuth, soda, salol, and papain was prescribed to be taken three times a day. After a week the dietary was increased by the addition of fish, fowl, and toasted bread; and later by red meat and cooked vegetables. The bismuth mixture was replaced by the combination of papain, iron, and cannabis indica, and the bowels were regulated by means of compound rhubarb powder, taken according to requirements. In three weeks complete convalescence was established and the digestive functions were normal. All epigastric tenderness had disappeared and she could bear deep pressure without flinching.

CASE 5.—A young woman twenty years of age, ruddy, well nourished, and apparently vigorous.

Symptoms and history.—Two months ago her appetite began to fail, and for the past fortnight she had experienced pain in the pit of her stomach after every meal. The pain continued for three or four hours, and only subsided as the time for her next meal approached, unless vomiting occurred, by which it was at once relieved. It commenced in the epigastrium, but gradually extended through to the back, and was proportionate in degree to the kind of food taken. For ten days past sickness had become a pronounced symptom and had been welcomed by the patient as the speediest relief to her discomfort. Twice, if not three times, the vomited matter had been stained with blood, and on one occasion she observed that the morning evacuation of the bowels was black in colour. Coincidentally with her loss of appetite there had been failure of strength and disinclination for effort. Naturally energetic, she had of late become languid, irritable, and unfit for any work requiring concentration of energy. All her life she had been the victim of persistent constipation. On examination of the epigastric region there was considerable tenderness, which did not, however, appear to be concentrated in one spot, though it was greater to the left than to the right of the sternum. Pressure increased the tenderness and produced painful retching. The tongue was abnormally clean and so sensitive that warm or seasoned food dared not be put into the mouth. The apex beat of the heart was somewhat diffuse and the second sound was accentuated, but there was no bruit. There was imperfection of the respiratory murmur throughout the right lung, which did not expand as fully as the left. There was no derangement of the general nutrition. The urine contained an excess of phosphates. Some years ago she had gone through a serious attack of pleuro-pneumonia, from which she had made a slow recovery, but her life had been in other respects a healthy one. She had never before the present time suffered from derangement of her digestive organs. During the last year her work had been unusually arduous, and she had had to contend with an excessive amount of mental worry. Her family history was excellent.

Treatment and result.—A simple dietary was ordered of milk, eggs, clear soups, and farinaceous food; and she was advised to give up work entirely for a time. Papain, iron, cannabis indica, and strychnine were prescribed three times a day, with an aperient dose of euonymin, colocynth, and rhubarb every alternate night. After a week fish, fowl, stewed fruit, and cooked vegetables were allowed. The necessity for a regulated daily amount of open-air exercise was also insisted upon. In fourteen days she was so much better as to be able to resume ordinary food, and at the end of three weeks she was perfectly well and returned to the full duties of her occupation.

CASE 6.—A woman thirty-three years of age, thin, anæmic, and with a careworn, cachectic appearance.

Symptoms and history.—Her illness dated back four years, during the whole of which time she had been a martyr to dyspeptic troubles. She had now given up her work and come home in the hope of finding permanent relief from prolonged rest. She suffered from continual epigastric fullness and pain, which were so aggravated by the taking of food that she had been obliged to live almost entirely on milk, and even that at times had produced acute suffering. Since she first became ill every attempt to take solid food had been followed not only by pain but also by sickness and retching.

There had been slight hæmorrhage on several occasions, but she did not think the amount had ever exceeded a few ounces. Her nights had been sleepless, and she had experienced such misery from palpitation as to make her fear she was the subject of some serious form of heart disease. She had all her life suffered from dysmenorrhœa, but the amount of loss at each menstrual period had for over two years been markedly diminished. She had been subject to unaccountable attacks of vertigo, which had always occurred without warning and had often been so bad as to compel her to lie down. They had always been followed by distressing head symptoms, which she had difficulty in describing otherwise than by saying that her head felt "empty and as if it did not belong to her." She distinctly said the discomfort was not pain. Periodically she had an attack of diarrhœa, but as a rule her bowels were constipated and difficult to keep right. She had become very thin and felt unfit for any but the slightest exertion—indeed, if she followed her inclination she would keep to her bed entirely, because only there was she comfortable. She suffered from mental depression, amounting occasionally to mild melancholia. Her epigastrium dare hardly be palpated, and at two separate and circumscribed places near the middle line she could not bear pressure. Even the most gentle examination caused pain, which lasted for an hour or more and produced a continued feeling of deathly sickness. The stomach was distended and tympanitic. Her tongue was slightly coated on the dorsum, but was abnormally red round the edges; it was also dry and shrivelled. Her heart sounds were clear, but the impulse was feeble. The pulse was soft and rapid. There was some decrease in the area of liver dulness, but this was difficult to determine accurately on account of the distended state of the stomach. The urine contained an excess of urates. She had always been a most active person, and though possessed of a highly strung and sensitive nature she had been able to battle comfortably with the difficulties of her life and had never been ill till about four years ago, when, after a long spell of laborious and anxious duty, she broke down and first manifested the symptoms of her present illness. Her family history was highly neurotic, but it was not otherwise remarkable. In the course of this illness she had been better and worse, but never well, and twice before she had given up work for a period of six weeks.

Treatment and result.—Absolute rest in bed was advised, and boiled milk with lime water to the extent of from three to four pints in twenty-four hours, to be taken cold and sipped in small quantities at a time; also meat juice every four hours. One dose of calomel was ordered at bedtime the first night, and every morning an enema of glycerine and hot water. A fly blister was applied over the whole epigastrium. Every six hours she was instructed to take in milk a powder composed of carbonate of bismuth, sulpho-carbolate of soda, papain, and morphia. After a week prepared foods, meat jellies, and clear soups were added to the dietary, and the powders were replaced by a mixture containing strychnine, morphia, and bichromate of potassium. In another ten days the combination of papain, iron, and cannabis indica, to which in this case some arsenic was added, was resorted to. Farinaceous food, white fish, and the simpler meats were allowed, to be followed gradually by further additions as the comfort of the patient and the tolerance of her stomach permitted. At the end of two months she was able, with moderate care, to digest ordinary food. She then resumed her occupation. Her work was modified, and for another month she continued her medicine and still exercised a wise control over her food. In three months she was well and vigorous and able to leave physio alone. She has continued so, and has since reported herself as having regained her normal weight and strength.

CASE 7.—A young woman aged twenty-four years, of bright complexion, tall, and delicate-looking.

Symptoms and history.—Three months ago she first complained of discomfort after her meals. It had become worse daily, and was now accompanied by fullness of the stomach, together with heartburn and frequent attacks of sickness. She was never free from nausea. Her bowels were constipated and she had no appetite for food. Menstruation had been excessive for years, but for some months past the periods had recurred as often as every ten days. She had continual headache, which was worse in the evening than the morning and was relieved by sleep. There was no generalised tenderness and no apparent undue distension of the epigastrium, but to the left of the ensiform cartilage there was

one spot exquisitely tender, which she disliked having touched. Her tongue was fissured, flabby, and raw. There was a loud hæmic murmur in the large vessels and a systolic bruit at the apex, which was situated outside the nipple line. The right edge of cardiac dulness extended to the right margin of the sternum. There was accentuation of the second cardiac sound. The urine contained a distinct ring of albumen. She had twice suffered from hæmatemesis, the last occasion being between two and three years ago, when the bleeding was severe and the convalescence slow. From both attacks her recovery seemed to have been perfect, and she was able in the interim to live as usual and to comfortably digest ordinary food. She had been subject to attacks of rheumatism, but never in an acute form; and in winter time she frequently suffered from a hacking and obstinate cough. Her family history was phthisical.

Treatment and result.—A milk dietary for ten days, to be followed thereafter by gradual additions of solid food, was advised. Papain, iron, and cannabis indica were ordered from the beginning, with an iron and aloes pill for aperient purposes as often as necessary. At the end of a fortnight she was very much better, and in a month she was well except for the mitral murmur, which probably had been of old standing.

CASES 8, 9, AND 10.—These were all mild cases, which need not be detailed. In none of them had there been hæmorrhage, but all manifested the usual symptoms indicative of probable gastric ulcer, and in each the treatment by papain, iron, and cannabis indica produced an eminently satisfactory result in a period ranging from two to four weeks. Cases 8 and 9 were male patients.

General remarks.—The symptoms in these ten cases were so characteristic that it can hardly be doubted that in all of them the pathological condition was one of ulceration, actual or threatened, of the mucous membrane similar to that found post mortem in Case 1 of the series. The results, moreover, of treatment by papain, iron, and cannabis indica are so striking as to make it probable that in such a combination we have a powerful and useful weapon with which to combat a very intractable disease, and one which, perhaps more than most others, impairs the usefulness of the unfortunate victim and renders his or her life a burden. It would seem doubtful whether many cases of so-called irritative dyspepsia may not in reality be due to this definite lesion of the mucous membrane in a latent condition. Hæmatemesis is not necessarily present in every case of even acknowledged gastric ulcer, and in its absence it must always be a matter of difficulty to decide whether the train of symptoms owes its cause to a simple catarrh or to organic change in the substance of the stomach wall. The occurrence of hæmorrhage clinches the diagnosis; but where remedies, useful in cases about which by reason of the hæmatemesis there can be no doubt, give equally good results in allied cases which fall short of the confirmatory evidence afforded by the bleeding, we may assume that such cases may owe their symptoms either to an early stage of the same condition or to an accomplished lesion of the surface so chronic and indurated as to prevent actual loss of blood. By some observers the persistence of pain in patients who have admittedly suffered from gastric ulcer has been ascribed to imperfect movement of the stomach walls consequent upon the interference of the resulting cicatrix; but the histories of Cases 2, 3, 6, and 7 would rather indicate either imperfect healing or the occurrence of another patch of ulceration as the more probable explanation of the continuance of this symptom. Were this not so it is hardly conceivable that each of these cases could have recovered so thoroughly, because it seems certain that in several of them there must have remained one or more cicatrices of considerable dimensions. In all this series, putting on one side the differences of detail required by the idiosyncrasies of each, the plan of treatment has consisted in the exhibition of a mixture of iron, papain, and cannabis indica, generally in pill form, and with varying quantities of each of the ingredients. As the large proportion of such ulcerations occur in anæmic patients the *raison d'être* of the iron is manifest. It may be that in some cases iron is not indicated at all by the existence of any appreciable anæmia; but even then it is probable that the blood is impoverished to some degree, and that the hæmatinic properties of the drug not only restore this depreciation of quality but also, in a secondary way, promote the healing process at the site of lesion. The cannabis indica is useful as a sedative to the stomach walls, as a controller of its muscular action, and as a prop to its nerve-supply, while it

is also fully recognised as a direct promoter of appetite. Lastly, papain, which is the most important member of the trio, probably has a complex effect on the curative process. It is well known that when a solution of papain is painted over a fissured or ulcerated tongue it rapidly provokes cicatrization. The drug is also of value as a speedy solvent of dead tissue, and to some extent it is credited with antiseptic and tonic properties. Its great use, however, medicinally has hitherto been as a digestive ferment, and its activity in this respect would seem to exceed that of pepsin, pancreatin, or any other known agent. If all these powers of papain be admitted it is easy to conceive a reasonable hypothesis to explain the happy results afforded by it in cases of gastric ulcer, particularly when it is combined with other drugs such as those indicated, which by their collateral effect assist and intensify its action. This hypothesis is strengthened by the post-mortem evidences in Case 1 and still further confirmed by the marked alleviation, if not permanent cure, in the other cases above narrated.

Warwick.

CASES ILLUSTRATING THE SURGERY OF THE KIDNEY.

By J. KNOWSLEY THORNTON, M.B., C.M. EDIN.,

CONSULTING SURGEON TO THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN, NEW HOSPITAL FOR WOMEN, AND GROSVENOR HOSPITAL FOR WOMEN.

(Continued from p. 213.)

CASE 31.—This case is in many respects a very remarkable and very interesting one, and I must give it in a little more detail than is necessary with most of the cases. A married woman aged forty-four years, mother of two children, both dead, the youngest a daughter, who had died from phthisis aged two and twenty only the year before I was asked to see the patient by Dr. Ferrier. The patient's father died from bronchitis aged seventy years; the mother was still alive; one brother and one sister were also living and well, and one sister was dead. In 1873 when travelling abroad the patient had a severe attack of abdominal pain, so-called "gastric," brought on by a chill, and after this menstruation was for some time very irregular. Before this illness, in 1866, she was riding a great deal a horse that "buck-jumped and did extraordinary things" (she rode this horse from 1863 to 1867), and she then noticed a lump in her right side, which she could sometimes find and sometimes not. She used to have pain in the side and could then feel the lump. In 1881 she got another chill just before the period, and had a severe attack of peritonitis and was laid up for three months; after this the periods again became very irregular and excessive, and there were pain and lameness of the left hip, and just before our first consultation the right hip had also begun to be painful. Dr. Ferrier asked me to examine the pelvis, various troubles for which she had been under his care having entirely resisted all treatment. I found a normal uterus in good position—a large prolapsed and somewhat fixed left ovary and a small right ovary embedded in adhesions and with a distended tube. Any pressure on the ovary caused severe pain and nausea. I advised removal of the ovaries and tubes, and operated on Feb. 24th, 1887. The whole pelvis was a matted mass of dense fibrous adhesions, and I removed two distended tubes (hæmato-salpinx) and, as far as I could, both ovaries; but the right one was so embedded in adhesions that I had to scrape it away, and I have no doubt that more or less ovarian tissue was left behind. She made an excellent and uncomplicated recovery until she went downstairs, when she began to vomit her food. She ate and enjoyed her food, but within a few minutes of swallowing it she vomited without nausea and without strain. She went back to bed, the vomiting became constant, and, to make a long story short, she was in bed for over a year, only kept alive by nutrient enemata and the small residuum of food retained by the stomach after a meal. This was extremely small, as we proved by washing it out for examination. The patient became a perfect skeleton, but was bright and cheerful, and even selected her meals with considerable care and enjoyed them, though they were vomited in less than a quarter of an hour. She was seen in consultation with Dr. Ferrier and myself by

most of the leading physicians in London at different times, and was constantly watched by both of us, but no one ever suggested any remedy that helped her or us. One day, fifteen months after the operation and fourteen after the commencement of the vomiting, it ceased as suddenly as it began, and three meals were taken in succession, and, though so extremely emaciated and weak, she sat up to eat them and remained sitting bolt upright for twenty minutes after, which, she said, seemed to settle her stomach. I have already mentioned a lump in her right side; this I could not find before the operation, and I did not then attach sufficient importance to it to look for it when I had the abdomen open—indeed, my hands were quite sufficiently full with what I had to do in the pelvis. But during this long illness, and when she was emaciated, we found a large, mobile, and somewhat tender right kidney. I may mention that the urine examined before the operation was a good average healthy specimen. She had been having massage shortly before I first saw her, and while this was going on she had for the first time noticed some slimy matter in her urine. There was nothing of the kind when I saw it. These are important facts when we come to the further history and conclusion of the case. When she had quite recovered her usual health she began to have irregular but pretty severe and prolonged uterine losses (probably due to the presence of remains of the right ovary and the irritation caused by changes around the ligatures used and from the contraction of scar tissue). I had always been inclined to regard the vomiting as a reflex result of some such irritation, and had at one time thought of a fresh exploration of the pelvis, but she seemed too emaciated and weak for any serious operation. These losses were an annoyance and disappointment to her, and I saw her from time to time and found that the right kidney was still palpable and tender, but it seemed to give her no trouble. In the early spring of 1889, about a year or less after the cessation of the vomiting, I was asked by Dr. Ferrier to see her again in consultation as the sickness had returned. It was soon as bad as ever, and both the patient and myself now directed much of our attention to the tender right kidney as a possible cause of it, and at last, as she was rapidly losing ground, I urged its removal and a thorough exploration of the pelvic cavity. I operated on June 24th, 1889, Mr. Murray giving chloroform, Mr. Malcolm assisting, Dr. Frank of Cannes and Dr. Ferrier being also present. I found nothing in the pelvis except little shot-like prominences where some of my ligatures were buried, and there was a little omentum adherent to the abdominal scar. The right kidney was a mere thin shell or bag of putty-like and calcareous matter; it was mobile, but very adherent, with fibrous bands and membranes. As I was working through a rather small median opening (I had merely reopened the old incision), I determined to incise the loin and thus extract the kidney. This I did with considerable difficulty, owing to the dense nature of the adhesions. The ureter appeared perfectly healthy, and this made me doubt whether the disease had been originally tuberculous. I have never in any other cases seen a healthy ureter with a tuberculous kidney. I planned it out in the loin wound. On making a final intra-peritoneal examination I found a large opening in the peritoneum over the site of the right kidney (a fact to be kept in sight when discussing lumbar *versus* abdominal nephrectomy) and a curious thick, strong, fibrous band stretching across the pelvis in such a way that it must have interfered much with all the pelvic organs, and it especially dragged on the right ureter. The kidney after removal was found to be a mere thin shell without a vestige of kidney tissue, its whole interior being occupied with a mixture of putty-like and calcareous material. The patient made an excellent recovery without any bad symptoms, in spite of a partial reopening of the wound after the removal of the sutures—an accident due, I believe, to imperfect union of two edges of scar tissue. I did not in this case, as I usually do in performing a second operation, entirely dissect out the old abdominal scar. Another unfortunate result of this bit of bad practice was a ventral hernia which I had to operate upon two years later, giving her the discomfort of a third operation. She has remained in very good health, but has never quite lost the hip lameness.

The urine examined by Mr. Malcolm at the end of 1887—nearly a year after the first operation and when she was in an extremely exhausted condition from the constant vomiting—was of a good amber colour, acid reaction, sp. gr. 1023, with only a slight deposit, which consisted of bladder and

renal epithelium and numerous oxalates. There was a mere trace of albumen. Evidently little or nothing was getting into the bladder from the right kidney either at this time or when I tested it before the first operation. It was very frequently examined during the second vomiting, and presented practically the same conditions. It seems perfectly plain from this remarkable case that the kidney, though entirely destroyed as a secreting organ, may still, when unduly mobile, give rise to the most severe reflex phenomena. All who devote special attention to the kidney must be struck with the very wide range of reflexes which are possible with an unduly mobile organ. This case seems to mark the extreme limit of digestive disturbance, and it certainly is strange that this limit should have been reached with an organ so completely destroyed by disease, and I am inclined to question whether it was the kidney or the healthy ureter dragged upon by the pelvic band which was the cause of the sickness. I have in one other case noted some troublesome sickness following nephrectomy in the case of a young woman whose ureter, fixed in the lower angle of the abdominal incision, remained for a long time patent, and required the occasional passage of a fine gum elastic bougie down it into the bladder to clear it of accumulating secretions. If we regard the alternately kinked or stretched ureter as the cause of the troubles in mobile kidney, we have an immediate explanation of the persistence of pain and other troubles when the kidney is sutured too low in the operation for its fixtue (nephrorrhaphy). Such a case is now under my care, and I have failed to entirely cure it by freely dividing adhesions and making a fresh suture because I altogether failed to get it pushed high enough up, though I appeared to have freed it thoroughly. To go back to the early history of the present case, we have a healthy girl riding a rough horse for some years, regardless of times and seasons (I refer to menstruation). This rough riding is, as I have already in a previous paper pointed out, an evident starting point in some cases of mobile kidney, nothing being more likely than that the muscular actions necessary to keep one's seat on a "buck-jumper" should produce dislocation of the kidney. Then followed two attacks of abdominal inflammation, both, as evidenced by the irregular menstruation, seriously affecting her pelvic organs. What more likely than that this mobile kidney, troubled by alternate distension to pain and collapse, already probably hydronephrotic, should suffer seriously from these attacks of surrounding inflammation (peritonitis)? The hydronephrosis becoming a pyonephrosis in one or other of them, whether tuberculous or simple inflammatory. The kidney was gradually destroyed without attracting much attention, and during this time she bore two children, both of whom died young and one from undoubted phthisis. The destroyed kidney passes into the background, while the ovaries in their more active life claimed attention; then the kidney, pressed down and irritated by the constant vomiting, again became palpable and painful. The slimy matter in the urine after the course of massage explains why the kidney was not a prominent feature at the time of my first examinations: its contents had been pressed out through the ureter, and in a flaccid condition such a soft bag as it was would readily escape touch when examining the abdomen unless it was tender and so called attention to its presence. I may mention that the irregular uterine losses gradually came less often and then ceased, a sequence I have before noted in cases in which small portions of ovarian tissue were left behind and were presumably the cause of the irregular metrorrhaxis. The commencement of the vomiting, when she first began to wear a tight abdominal belt and move about after three weeks' perfect quiet on her back, is much easier to understand than the sudden cessation, and the sudden recommencement when she appeared to be in perfect health.

CASE 32.—This is a very unfortunate case and its record is one which may, I hope, help both myself and others to avoid attempting surgery in similar cases. A woman aged forty-three years, single, consulted me in June, 1889, as to a large swelling in the abdomen. She had first noticed some swelling in the same situation ten years before her visit to me, and could not in any way account for its commencement. She suffered much from constipation and from an irritable bladder, having to get up during the night to pass urine, and sometimes frequently. Menstruation had commenced late and was always excessive. The urine was of low specific gravity 1009, hazy, barely acid, and contained an eighth of albumen. Seventy-three ounces passed in twenty-four hours contained 245 grains of urea. Another specimen examined three weeks later contained nearly a

quarter of albumen and some red blood cells. I came to the conclusion that the case was one of sarcoma of the right kidney, and in this diagnosis Sir Andrew Clark, who saw the case with me, concurred, and we advised its removal. The left kidney was also distinctly large, but this I thought was probably due to compensatory hypertrophy. The slow growth of the tumour made me hope that it was a sarcoma of the capsule, or of the supra-renal capsule, similar to others in which I had obtained excellent results by operation. It was a very soft kidney and there was an indistinct fluctuation, or thrill, which rather suggested that some cystic change was taking place. I operated on July 11th, 1889, by Langenbüch's incision, and as soon as I had exposed the kidney saw that I had to deal with that rare disease multiple cysts of the kidney. The whole organ was a mass of small cysts crowding upon one another and pressing one another out of shape, so that its exterior presented the appearance of a tessellated pavement. Passing my hand across to the left side of the abdomen I found the other kidney unmistakably in an early stage of the same disease, though there was still in it more healthy than diseased tissue. Clearly I ought to have closed my incision, for I was face to face with an incurable disease of both kidneys, but I thought that, as the one was already practically destroyed and giving her pain and discomfort, she might live longer without it. It enucleated very easily; indeed, I never had a simpler nephrectomy. There was only a small opening in the outer layer of the meso-colon, and this seemed to lend itself so well to complete shutting off from the general cavity of the peritoneum that I sutured it into the abdominal wound and drained the sac with a glass tube, a second mistake, as will be seen immediately. By tapping successive cysts I obtained four pints of fluid from the kidney, and it was still very large when I removed it. The vessels were tied separately and the ureter pinned out beside the sac. The patient began to retch directly after the operation and vomited persistently till I reopened the wound on the fourth day and found an immensely distended cæcum pressing on and obstructing the ileo-cæcal valve, the whole being due to the hooked-up position of the ascending colon from my sutures. I need not give in detail the downward progress of the case during these four days; it was unmistakably a case of obstruction, but I hesitated to reopen the wound, partly because we got large actions by gruel and turpentine enemata, though never any passage of flatus, and partly because I feared the effect of a further operation on the remaining kidney. There was no fever all through, but on opening and emptying the cæcum I found a patch of gangrene the size of a sixpence where the pressure had been most severe; this was excised and the incision closed with a row of Lembert's sutures, a second row of interrupted sutures bringing the peritoneal surfaces together as a support, my incision into the cæcum being closed in the same way. On putting a tube into the pelvis to more thoroughly drain the peritoneum I found that it was blocked with adhesions, the uterus, ovaries, and bowels being all bound together, and I then learnt for the first time that the patient had nearly died from obstructed intestine once before. The one kidney continued to work well, but she did not rally well from this second operation, and she died quite suddenly on the following day while telling me in a good strong voice about her previous illness.

I made two or perhaps three mistakes in this case. 1. I ought to have closed my incision when I found what the nature of the disease was. 2. I ought not to have sutured the edges of the sac into my peritoneal wound. I have over and over again decided that this is bad practice, and yet now and again some specially favourable case for shutting off the peritoneum tempts me to try it once more. In this case it caused a fixed bend in the ascending colon, which dragged upon the cæcum already held below by pelvic adhesions, and the more it distended the more it tended to close the ileo-cæcal valve. 3. I ought to have had the courage of my opinion and reopened the wound and freed the bowel sooner—i.e., directly I became convinced that there was obstruction. There is no condition in surgery in which hesitation and delay are likely to take away the chance of success so decidedly as in acute obstruction of intestine, and there is no condition in which patience and waiting, with a judicious use of atropine and morphia and of turpentine enemata, are so likely to be rewarded as in chronic obstruction, especially if it is in the very smallest degree incomplete.

(To be continued.)

THE INFLUENCE OF THE FORCE OF GRAVITY ON THE CIRCULATION.¹

By LEONARD HILL, M.B. LOND.,

ASSISTANT PROFESSOR OF PHYSIOLOGY, UNIVERSITY COLLEGE, LONDON,
AND GROCERS' RESEARCH SCHOLAR.

THE effect of position of the body upon the circulation of the blood is a matter of daily observation with the physician and surgeon, but it has been curiously neglected by physiologists. So far as my researches into the history of the subject go the mere facts that the feet-down position lowers arterial pressure and that the feet-up position heightens it are almost all that has been determined. In 1885 Hermann placed the subject in the hands of two pupils, Blumberg and Wagner, with the object of investigating the dynamic and hydrostatic effects of gravity on the circulation. The hydrostatic moment is the altered relationship of level between the given spot on the artery (where the manometer is placed) and the rest of the vascular system. The dynamic moment is the altered relation between pressure and resistance produced indirectly by the change of position on the heart beat, the filling of the heart, the vaso-motor nerves, &c. Hermann instructed his pupils to find the indifferent point of the circulatory system, in order that the hydrostatic effect might be eliminated and the dynamic effect alone studied. Blumberg and Wagner determined the indifferent point by filling the circulatory system of the dead animal with salt solution and then by shifting the position of the axis round which the body was turned. I have found that on attempting, according to Wagner's method, to fill the circulatory system of the dead animal with salt solution the arterial part of the system does not remain filled, for the salt solution rapidly leaks into the splanchnic venous area. By alternately placing the animal with feet down or with feet up a pumping action is produced which gradually forces the salt solution out of the arterial system into the venous side, where it remains. The indifferent point cannot, therefore, be found on the dead body. Further, if it were possible to find the indifferent point on the dead body, the indifferent point on the living body could not be deduced therefrom, because such indifferent point depends on the coefficient of elasticity, which must constantly alter in the living animal with every alteration of the arterioles by vaso-constriction or dilatation. As regards the dynamic effect of gravity on the circulation, therefore, the work of Blumberg and Wagner cannot be accepted. My attention was first drawn to the influence of gravity upon the circulation by observations which I made upon the normal intra-cranial tension in a patient under the care of Dr. Clape Shaw. The patient had been trephined, and Dr. Shaw asked me if I could estimate his normal intra-cranial pressure. I did so by an adaptation of the method for investigating intra-cranial pressure described by me in the Proceedings of the Royal Society, vol. IV. I found that the pressure was negative while the man sat upright, but that it became positive as soon as the head was bent down towards the knees, and on any expiratory effort. The air-bubble index in the apparatus exhibited large cardiac and respiratory undulations. Experimenting on dogs, I found that exactly the same thing occurred. The normal cerebral pressure became markedly negative in the feet-down posture and positive in the feet-up posture. For the further investigation of the subject I constructed an animal holder which could be swung round a horizontal axis. In this axis the cannula connected with the vessel under observation was always placed, and the cannula itself was connected with a fixed hydrostatic manometer. The "hydrostatic and dynamic moments," to use Hermann's expression, were investigated and separated, not by attempting to find the indifferent point, but by carefully observing the effects of dividing and stimulating the vagus and splanchnic nerves and spinal cord, and by watching the influence of anaesthetics, curare, and asphyxia. The research has been carried out upon rabbits, cats, dogs, and monkeys, and the same general results have been obtained from all. The animals were anaesthetised in all the experiments, and were placed upon a board with the limbs fully extended in the same direction as the longitudinal axis of the body. The experiments group themselves under the following headings:

I. Effects on the circulation.—1. Normal effect on arterial

¹ Abstract of a paper read before the Royal Society.

pressure: (a) with carotid artery in axis, (b) with femoral artery in axis, (c) with splenic artery in axis. 2. Normal effect on venous pressure: (a) with splenic vein in axis, (b) with femoral vein in axis, (c) with torcular Herophilli in axis. 3. Influence of anæsthetics. 4. Effect of dividing the vagi. 5. Effect of dividing the spinal cord: (a) influence on heart. 6. Effect of dividing the splanchnics. 7. Influence of respiration and asphyxia. 8. Influence of curare.

II. *Effects on respiration.*—1. Normal effects. 2. Effect of dividing the vagi.

The venous pressures were recorded by means of a manometer filled with saturated sulphate of magnesia solution and placed in connexion with a delicate tambour or piston recorder. The cerebral venous pressure was taken in the torcular Herophilli by the method described by me in the before-quoted paper. The respiratory tracings were taken by means of a broad band of strapping passed round the thorax and connected to either side of a Paul Bert tambour. The changes of position prevented the use of any more accurate method for recording the respiration. The results of the research are shown in a series of tracings, from which the following conclusions are drawn:—(1) That the force of gravity must be regarded as a cardinal factor in dealing with the circulation of the blood; (2) that the important duty of compensating for the simple hydrostatic effects of gravity in changes of position must be ascribed to the splanchnic vaso-motor mechanism; (3) that the effects of changing the position afford a most delicate test of the condition of the vaso-motor mechanism; (4) that the amount of compensation depends largely on individual differences; (5) that the compensation is far more complete in upright animals, such as the monkey, than in rabbits, cats, or dogs, and, therefore, is probably far more complete in man; (6) that in some normal monkeys over-compensation for the hydrostatic effect occurs; (7) that in the normal monkey and man gravity exerts but little disturbing influence owing to the perfection of the compensatory mechanism; (8) that when the power of compensation is damaged by paralysis of the splanchnic vaso-constrictors, induced by severe operative procedures or by injuries to the spinal cord, by asphyxia, or by some poison such as chloroform or curare, then the influence of gravity becomes of vital importance; (9) that the feet-down position is of far greater moment than the feet-up position, because when the power of compensation is destroyed the blood drains into the abdominal veins, the heart empties, and the cerebral circulation ceases; (10) that, generally speaking, the feet-up position occasions no ill consequence; (11) that the horizontal and feet-up positions at once abolish the syncope induced by the feet-down position by causing the force of gravity to act in the same sense as the heart, and thus the cerebral circulation is renewed; (12) that firmly bandaging the abdomen has the same effect (while the heart remains normal, and so long as the mechanical pressure is applied to the abdominal veins, the pressure cannot possibly fall); (13) that if the heart is affected, as by chloroform or curare poisoning, the restoration of pressure is incomplete, and it is possible that the heart may be stopped altogether by the rush of a large quantity of blood, caused by too rapid an application of pressure on the abdomen (more work would be thrown upon the heart than in its impoverished condition it could perform); (14) that vagus inhibition and cardiac acceleration are subsidiary compensatory mechanisms in the feet-up and feet-down positions respectively; (15) that chloroform rapidly paralyses the compensatory vaso-motor mechanism and damages the heart; (16) that ether, on the other hand, only paralyses the compensatory vaso-motor mechanism very slowly and when pushed in enormous amounts; (17) that the vaso-motor paralysis induced by these anæsthetics lasts for some considerable time after the removal of the anæsthetics; (18) that chloroform can, by destroying the compensation for gravity, kill the animal if it be placed with the abdomen on a lower level than the heart; (19) that elevation or compression of the abdomen immediately compensates for the vaso-motor paralysis produced by chloroform; (20) that compression or elevation of the abdomen, coupled with artificial respiration and with squeezing of the heart through the thoracic walls, is the best means of restoring an animal from the condition of chloroform collapse (these results agree entirely with McWilliams', and are opposed to those of the Hyderabad Commission); (21) that the feet-down position inhibits respiration, and the feet up position accelerates

it; (22) that these respiratory results probably depend upon the stimulation of sensory nerve endings by changes of tension brought about by the alterations of position, because the results are abolished by dividing the vagi; (23) that in the feet-down position the respiration is thoracic in type, and the abdomen is retracted; in the feet-up position the respiration is diaphragmatic and the abdomen freely expanded; (24) that these types of respiration tend to compensate for the effects of gravity on the circulation, for the retraction of the abdomen in the feet-down position mechanically supports the abdominal veins, whilst the thoracic inspirations aspirate blood into the heart. In the feet-up position the full and free expansion of the abdomen withdraws all obstacles to the compensatory dilatation of the abdominal veins.

[In the last part of the paper the medical aspects of this research are discussed. It is suggested that emotional syncope is due to paralysis of the splanchnic area, and a case is quoted where compression of the abdomen immediately removed the syncopal condition. The same treatment, or that of elevation of the abdomen, is suggested for conditions of shock, chloroform collapse, and after severe hæmorrhage. Finally, a parallel is drawn between some of the results of this research in reference to monkeys and those obtained by Dr. George Oliver on man, by measuring the diameter of the radial artery with his ingenious instrument, the arteriometer.]

A CASE OF MYOSITIS OSSIFICANS.

By STEPHEN PAGET, M.A. OXON., F.R.C.S. ENG.,

SURGEON TO THE WEST LONDON HOSPITAL AND THE METROPOLITAN HOSPITAL.

THE patient is a boy aged seven years and six months, thin and small, but fairly strong and active, and very intelligent; his general health is not impaired. His father, aged about forty years, is in good health and has never suffered either from gout or from rheumatism, but the boy's grandfather and grandmother both had rheumatic fever twice. The child's mother, aged about thirty-five years, is in good health, and has never had rheumatism; but her mother had rheumatic fever. One of her sisters died from cancer of the breast, and another died at the age of thirty-eight from "ulceration of the bowels." The patient is the eldest of three children; the others are healthy and have no deformity of the toes. The mother has not lost any children, and has never had a miscarriage. The boy was healthy during the first years of his life. He had measles when six years and six months old. The deformity of his toes was noticed a week after birth. There is no history of any injury preceding his present disease. It began with a swelling behind the left ear when he was four years and six months old. The growths of bone in the pectorals and down the spine came early in the disease. His mother is certain that the growths used to shift their places, disappearing at one place and appearing at another; but their appearance does not seem to have been preceded by pain or swelling.

Condition in 1892.—The patient was at this time five years and nine months old. (Dr. Rayner of Stockport, who has kindly allowed me to publish this case, let the child be under my care in the Metropolitan Hospital in the summer of 1892.) The following note was made at the time: "He holds his head in the position of wryneck, from contraction of the left sterno-mastoid. In each pectoral muscle, at the anterior fold of the axilla, are irregular bony nodules moving slightly with the muscles. On the right side these nodules are felt all over the pectoral muscle and are especially marked towards its insertion; here they are continuous with plates of bone under the deltoid and along the latissimus dorsi. Nodules are also felt on the origin of the serratus magnus. The latissimus dorsi presents a sharp ridge in the axilla, and is hard, but not prominent, down to the angle of the scapula; and there are two prominent masses, not fixed to bone, beneath the angle of the scapula. The scapular muscles themselves do not appear to be affected. On the left side the pectoral muscle is also infiltrated with bone; it is more nodular than the right pectoral, and the bony growths towards its insertion are more prominent. They are continuous, as on the right side, with bone in the fascia beneath the deltoid, and, though this is not quite certain, with the latissimus. The disease in the left latissimus is

most apparent below the inferior angle of the scapula; but it is less marked here on the left side than on the right. The left biceps is also affected. Crapitus is felt

FIG. 1.

To show the contraction of the left sterno-mastoid, the masses of bone in the latissimi dorsi, and the extreme amount of abduction of the arms obtainable.

FIG. 2.

To show the abduction of the arms—front view.

when these growths are moved. Down each side of the spinal column is a hard ridge, more marked on the left side than on the right, which seems to be part of the

latissimus dorsi. The trapezius is healthy. In each posterior triangle of the neck there is an ill-defined hardness. The right sterno-mastoid is healthy; the left is very much shortened, but no bone is felt in it save one very small nodule in its anterior edge, about an inch above the clavicle. From the anterior fold of each axilla, between the nipple line and the axillary line, a hard vertical cord, about the thickness of a No. 4 or 5 English catheter, runs straight down over the ribs and the abdominal wall, and fades away about the level of the iliac crests. The right cord is somewhat more distinct than the left; they are slightly movable and hard, but not so rigid as bone; they feel to the touch like the diseased lymphatics of cancer or like very atheromatous arteries. There are no bony growths either on the head, or in the abdominal muscles, or on the lower limbs." The child was in hospital for several weeks. Dilute phosphoric acid was given, but with no result.

Condition in 1894.—The patient has lately made a good recovery from a mild attack of scarlet fever. Figs. 1 and 2 show that the disease has advanced very slowly. The cords which ran down from the axillary folds have disappeared. The

FIG. 3.

To show the congenital deformity of the toes.

masses of bone are more fixed than they were, and most of them appear to be closely united to the skeleton. The breathing is almost wholly abdominal; the ribs move very slightly on deep inspiration. There is some enlargement of the right os calcis. The patient has deformity of the great toes; they are shortened and drawn inward toward the middle line of the foot, so that they come beneath and behind the second toes. The proximal phalanges seem small and ill developed. The heads of the first metatarsal bones are large. There is no deformity of the thumbs. The child has of late been taking thyroid extract, but without any result.

As regards the child's family history, it is curiously like that of the child whose case is recorded in vol. xix. of the Transactions of the Clinical Society of London. In that case the father was somewhat rheumatic; the paternal grandparents both suffered much from rheumatism; the maternal grandfather was said to have died from cancer in the chest. The congenital deformity of the toes, as is shown in Fig. 3, is exactly as it has been described in other cases of this rare

disease. It proves that we have to do with a disease that is congenital, but latent during the first years of life, and it may be reasonable to suppose that rheumatism in the father's family and cancer in the mother's family may work together to cause it. The appearance and disappearance of the hard vertical cords down the front of the trunk are worthy of note. It is possible even that the present fixity of the ribs may disappear. In a similar case in my father's practice, in 1883, the ribs were firmly fixed. Ten years later—in 1893—the patient wrote to him: "The whole front, from throat to pelvis, is much better. I remember your gesture of despair when you found no movement of chest and sides on my drawing a breath. Now the chest and sides move very well—not properly, of course, but not badly." This patient has been for some years under Mr. Horsley's care, who kindly lets me refer to the case. He has steadily taken salicylate of soda.

Wimpole-street, W.

CASES ILLUSTRATING THE RESULTS TO THE EMPLOYEES OF IMPERFECT VISION TESTING ON RAILWAYS.

By W. M. BEAUMONT, M.R.C.S. ENG.,
SURGEON TO THE BATH EYE INFIRMARY.

THE two following cases show, in the first place, the danger to which the travelling public are exposed by the present modes of vision testing adopted on most of our railways; and, in the second place, they exemplify the hardships which may ensue to those employes who have been imperfectly examined as far as their sight is concerned when first joining a railway company's service. The labours of a committee of the British Medical Association have aroused the companies, and alterations which are not improvements in any marked degree have been made on some of the lines. Unfortunately the Board of Trade have no power to compel the railway officials to adopt a uniform, or in fact any, standard, nor can they insist that the tests shall be applied by qualified medical men. In this matter the Board of Trade are all-powerful to recommend and all-powerless to order.

CASE 1.—A man joined one of our most extensive railway companies eleven years ago as a cleaner. No test was applied to his sight then, but seven years ago, when he hoped for promotion, he was examined by a superintendent and failed to pass his test. As a consequence he was put on shed work and has been kept on it ever since. His wages now, including extra work, are £1 4s. 3d. a week, with little chance of increase. Had he remained on the line he might have risen to £2 5s. a week. On examining him a fortnight ago I found his vision to be—right eye, $\frac{3}{6}$, left eye, $\frac{1}{6}$. There was compound hypermetropic astigmatism, five dioptries in one meridian and three in the other. With correction his vision could be brought up to the normal standard. Whether officials should be allowed to wear glasses is a question which seems to be worthy of consideration. In hypermetropes and those with hypermetropic astigmatism, where vision can be improved to the normal standard, there seems to be no great objection to them for certain duties. Certainly, he who with spectacles can see $\frac{3}{6}$ is likely to be more efficient than he who without them can only see $\frac{1}{6}$; and at present on many lines they are content to admit men who have only $\frac{1}{6}$. Hypermetropia and hypermetropic astigmatism are not usually conditions which are progressive, and in them there is no reason to anticipate future deterioration. Hypermetropes, it is true, are more likely to develop glaucoma, but this is a rare contingency; and if all hypermetropes are to be excluded from railway service where shall we find the supply of emmetropes equal to the demand, for it is manifest that myopes must be ineligible? On some foreign railways the use of spectacles is common, and the objection that the glasses may become obscured by condensation at a critical moment does not appear to arise. With regard to myopia it is to be remembered that it is a condition of refraction which cannot become less, but which most probably will increase, and which glasses very frequently cannot altogether neutralise.

CASE 2 is that of a colour-blind man who joined another of our large railway companies in 1864 as porter. He was examined as far as distant vision was concerned, and found

to be capable of counting the dots, but no test of his colour sense was applied. In 1871 he was appointed guard to a goods train, but no re-examination of his sight was made. In 1876 he was promoted to be passenger guard, when again no test was applied. In November, 1893, in consequence, he said, of an order from the Board of Trade, his vision was tested by an inspector, and he failed to distinguish between red and green. He was taken off duty for a fortnight and then received an order to resume his employment as guard, no further examination of his sight having been made. In September, 1894, without any warning or testing, he was removed from his post and made a ticket collector; his wages at the same time were reduced from £1 7s. a week to £1 3s., with no chance of an increase. Had he remained a guard he might have risen to £2 a week; but now, at the age of forty-eight, when he might fairly hope for a little more money and a little more comfort, all his prospects in life are suddenly blasted, and more than thirty years' faithful service, in consequence of the company's negligence at the outset, are rewarded by an atrophy of pay and a stasis of promotion. Here, then, we have a man quite incapable of distinguishing the most vivid red from the most verdant green—a "guard," as the great railway company under which he serves paradoxically call him—travelling up and down their line week after week, month after month, for twenty-three years. It would seem to an outsider to be a more accurate term if they called him a "passenger."

Cases such as those to which I have referred are not rarities in ophthalmic practice; they come before us again and again. The railway companies laugh at our remonstrances and ask for proof that accidents have occurred in consequence of the imperfect vision of their servants. The public refuse to be awakened, and until some serious calamity occurs it is probable that no change will be made.

Bath.

A CASE OF RAYNAUD'S DISEASE OR NEUROPATHIC GANGRENOUS TROPHO-NEUROSIS OF THE LOWER EXTREMITIES.

By JOHN HAROLD, L.R.C.P. LOND., M.R.C.S. ENG.,
MEDICAL REGISTRAR, CHARING-CROSS HOSPITAL.

A PALE, weak, and ill-nourished boy aged four years and one month was admitted to Charing-cross Hospital on June 24th, 1887, as a case of Raynaud's disease. His parents were healthy and the patient presented no manifestations of syphilis, and had previously enjoyed very good health, nor had he ever had chilblains. There was no history of shock, of fits, or of paroxysmal dyspnoea. The mother's confinement was natural. On June 12th he complained of severe pain in the left big toe and of tenderness of the left ankle, but no objective physical signs were detected. Nine days later the left ankle was noticed to be discoloured and the middle toe of the right foot and the right ankle were cold and of a bluish tinge. The right wrist was tender. The tip of the nose and helixes of both ears were normal. On June 24th the left foot as far as the tarso-metatarsal articulation was of a lilac or purple colour, the colour being most marked on the dorsal aspect, increasing in intensity towards the toes, the ends of these being almost black and the nail bed of each toe being livid. The affected areas were quite cold and anæsthetic, the upper limit of discolouration being encircled by numerous small bullæ; the junction area of normal and abnormal tissues being very painful. The toes of the right foot presented a somewhat similar discolouration. Just below the right external malleolus a purplish-looking spot about the size of a shilling was noticed, as also a similar one immediately below the internal malleolus. The nerve trunks of the upper and lower limbs were not tender on pressure, and no trophic disturbances were noticeable on the thighs, arms, or forearms. The wrists showed no signs of discolouration. Palpation could be detected in the posterior tibial and dorsalis pedis arteries. The urine was non-albuminous, non-saccharine, and there never was hæmoglobinuria. The eyes were normal and there was no tendency to conjunctivitis. The purple colour of the dorsum of the left foot was, on June 29th, replaced by a reddish colour, especially along the first

metatarsal bone, the temperature rising to 101° F. On July 1st the right foot was generally very much discoloured, of a dusky purple colour, shading off towards the normal skin into a violet or pinkish hue. The affected areas were very tender, the patient strongly objecting to their being touched. He was very restless and kept constantly moaning. The end of the ring finger of the left hand became discoloured on July 2nd; the nail bed looked cyanosed, the skin of the dorsum of the hand being of a deep dusky hue. Small phlyctenæ were noted on several of the toes. The pulse in the left radial artery could easily be felt; it was regular and of good force. The patient was better subjectively on July 3rd and the affected areas were less painful, the left ring finger being no worse. The right thumb and right forefinger presented a mottled pink appearance, but no improvement was manifested in the feet. The left foot was of a lobster tint, the ends of the toes being quite black and shrivelled. A large collar of various sized bullæ surrounded the left ankle. On July 9th the affected fingers were diligently fomented. The toes of both feet were mummified and were of a mahogany red tint; the bullæ about the ankles ruptured, leaving an offensive-smelling surface. The patient was kept under the influence of morphine, and the gangrenous areas treated antiseptically. The hands were apparently well by July 12th, but the toes had become of a blue-black tint. On July 20 the plantar aspect of the left foot was black, and its toes much shrivelled. A deep and clearly defined line of demarcation was evident at both ankle-joints, the ligaments of the joints were exposed, and the pain unabated. In about

a week's time spontaneous amputation of both feet had occurred, no surgical interference being required. The boy afterwards suffered from abscesses about the left hip and other parts, but eventually made a satisfactory recovery and seemed apparently none the worse in general health from his serious illness. The following points of interest were also noted. The heart and lungs were normal; the spleen was not palpable. The ungual phalanges showed no tendency to clubbing; the patient had not a high palate, and there was no muscular wasting, and at no time was there any effusion into the affected joints. The tips of the fingers and toes did not show any evidence of scars—little scars at or near the nail on the pulps of the fingers and toes being, as is well known, characteristic evidence of antecedent attacks of Raynaud's disease.

Remarks.—In the case just recorded the usual etiological factors in the causation of the affection could be eliminated, such as constitutional diseases, toxic agents as ergot and arsenic, febrile disorders, injury, and frost-bite. Writing on Raynaud's disease, Lancereux¹ says: "Without pretending that all symmetrical gangrenes of the extremities have a toxic origin, I affirm that the symmetry of these lesions is an almost unerring indication of the toxic nature of the original cause of the affection." The perfect symmetry of the affection in this case would accordingly be indicative of a toxic origin, and manifestly implies that the condition owned a

general and not a local causation. From the point of treatment the absence of objective signs before the actual appearance of gangrene and the presence of subjective symptoms as pain are noteworthy in the prodromal stage, as possibly benefit might follow the administration of vasodilators. It is by no means uncommon to meet with cases of Raynaud's disease as young as this patient. The late Dr. J. E. Morgan of Manchester² collected and analysed 93 cases. Of these the youngest was two years and a half old, and the oldest fifty-nine years; 54 were females and 39 were males. Twenty-four of the 93 cases were under the age of ten years, and the younger the patient the more acute was the disease. Mr. D'Arcy Power³ recorded a case in a girl aged four years and eight months. Dr. Abercrombie, in an interesting and instructive paper, has commented on the relation of hæmoglobinuria, malaria, and jaundice to attacks of Raynaud's disease. As already mentioned, nothing abnormal was noticed in the urine in this case, and no polyuria was recorded. In the case of two children suffering from Raynaud's disease Dr. Haig⁴ noted an excessive excretion of uric acid, and that the renal vessels were apparently constricted at the same time as the cutaneous. In a contribution to the subject of idiosyncrasies Dr. Solomon Solis-Cohen⁵ designates by the term "vasomotor ataxia" the condition of instability of the mechanism of the circulation present in certain individuals, and which is characterised by an abnormal readiness of disturbance, with tardiness of restoration, of the equilibrium of the cardio-vascular mechanism. Among the recognisable exciting influences he mentions temperature, especially cold, emotion, reflex excitation of an internal or visceral origin, and various toxic agencies. Vaso-motor ataxia, he considers, may be acquired, congenital, or inherited. It is often present in several members of the same family, and may in some cases be characterised by parietic phenomena; in others it may be of a spasmodic character. Thus, in Raynaud's disease, we have in the "local syncope" stage an example of the "constrictive" variety type. Cases of Raynaud's disease are not infrequently associated with various cutaneous affections, such as urticaria, mottlings, scleroderma, and telangiectases, but the present case was not associated with any such trouble. Mr. Hutchinson⁷ has recorded cases of symmetrical gangrene of the extremities with scleroderma, and also cases of diffuse morphea, preceded by conditions resembling Raynaud's disease; and he considers that we can gather round the interesting condition of neuropathic gangrene a family group of other conditions of equal interest and allied to it. The treatment adopted in the case related consisted in the free employment of morphine to subdue the pain and quiet the nervous system, the gangrenous areas being treated antiseptically. There was no reproduction of the gangrene in the stumps or in their vicinity, and the patient is now in the enjoyment of excellent health.

I am indebted to Dr. Mitchell Bruce for kind permission to publish this case.

Harley-street, W.

A CASE OF HYDROPHOBIA.

By SAMUEL LODGE, L.R.C.P. EDIN., M.R.C.S. ENG.

A BOY aged three years and five months was bitten by a dog in the palm of the right hand about two months before I saw him. He was immediately after being bitten taken to a druggist and the wound was freely cauterised. The hand and arm became inflamed, requiring to be poulticed for two or three days. After that time the wound healed, but the boy continued restless, jerking his limbs when he slept and moaning from time to time. He appeared to be pretty well, however, playing about as usual during the day. There remained a hardened spot on the hand all the while, which the child said was always painful. Nothing more particular was observed till Sunday, Jan. 13th. On the morning of that day the patient complained that his throat was bad, and in the afternoon a medical man was sent for. Some medicine was supplied, but not a drop was taken; he

tried many times to swallow a dose, but did not succeed. The next day the medical attendant was informed of the dog-bite for the first time; he did what he could to encourage the parents, who were much alarmed, and in their excited state it appears they actually forgot to tell him that the boy could not swallow the mixture. I was sent to the case on Jan. 14th at 3 P.M. The little patient was clinging very closely to his mother's neck; he made some inarticulate sounds and seemed greatly excited; he struggled continuously, but did not loosen his hold on the neck of his mother for an instant. A young woman washing dishes at a table near was splashing water about rather noisily. She desisted at my request, when the suffering child became quiet, relaxed his clasp, and smiled. There was a little girl in the room who now approached him. He gently stroked her face and hair, saying "Mary, Mary." After about ten minutes had elapsed a teaspoonful of water was offered him, but he no sooner saw it than he clenched his teeth and screamed. This was tried many times and in various ways, but he could not be induced to swallow the smallest quantity. He did himself try once or twice, but the effort was too great and ended in the same way. The jaws became fixed. There was spasmodic contraction of the thoracic muscles, and inarticulate cries. Exactly the same effect was induced by the mother of the child drinking some water when she endeavoured to persuade him to swallow. After every paroxysm there was a flow of saliva; sometimes viscid, sometimes frothy, and at other times watery. A clean handkerchief was handed to him, which he used unceasingly, wiping the mouth, and occasionally twisting and thrusting it into the throat till he appeared to be almost suffocated. When an opportunity occurred I examined the boy according to rule. The tongue was white and enlarged; the pulse was 100 and of fair volume; the temperature did not appear to be high (I could not ascertain it precisely, of course). The pupils were widely dilated. The expression of countenance was gentle and dreamy. The respiration was natural. The examination described in these few words was made at intervals and with great difficulty. The friends were recommended to have the case removed to the infirmary, and on this step being objected to Dr. W. A. Evans, medical officer of health for Bradford, was communicated with. My friend saw the patient in my absence, and thus had the opportunity of forming an independent judgment. At 5.30 P.M. my assistant, Mr. W. M. Muat, saw the child and observed the same train of symptoms. Perfect quietude was observed in the house. The patient frequently held out his hands for the glass of water always in readiness, but directly it was passed towards him he became violently convulsed. At 11.30 the same night he was visited again; he was then sitting on the couch in a peculiarly excited condition, tearing a newspaper into small pieces and talking incoherently; if his attention was suddenly attracted he became sensible for a moment, but relapsed immediately. He was never still, raising himself from his seat and falling back continually. Saliva was running from the mouth all the time; this he wiped away in the manner before described, forcing the handkerchief into the mouth and occasionally clutching his throat with both hands. The poor child expired quite suddenly about three o'clock next morning. There was no inquest.

I ought to mention that the dog, having bitten the child, was tied to a chair in the house of its owner, where it contrived to strangle itself. The body of the creature was sent to one of the destructors, so we had not an opportunity of examining it.

Bradford, Yorks.

THE REMOVAL OF PATIENTS TO ISOLATION HOSPITALS.¹

By G. H. FOSBROKE, M.R.C.S. ENG., D.P.H. CAMB.,
COUNTY MEDICAL OFFICER FOR WORCESTERSHIRE, AND PRESIDENT OF
THE WORCESTERSHIRE AND HEREFORDSHIRE BRANCH OF THE
BRITISH MEDICAL ASSOCIATION.

As the question of providing isolation hospitals is now coming prominently to the front, and I have been officially connected with two such institutions in rural districts for many years past, it occurs to me that my experience with

regard to the distances patients suffering from infectious diseases can be safely removed to hospital may be of interest to some. Having carefully considered the question, I have come to the conclusion that, assuming the locality to be non-mountainous, the highways good, and suitable ambulances (with attendant nurses) provided, such persons may without harm be removed as far as eleven or even twelve miles. Table I. shows the distances patients have been removed to six hospitals in Worcestershire and Warwickshire.

TABLE I.

	Alcester.	Evesham.	Kidderminster.	King's Norton.	South.	Warwick.	Total.
Under 1 mile	302	9	11	—	39	—	361
From 1 to 2 miles ...	73	61	28	85	95	268	610

Population of hospital district	17154	15072	38258	28300	29822	55200	—
Area in acres of hospital district	55071	47679	35129	22454	48693	68300	—

From this it will be seen that 242 patients in the above districts have been removed distances of from seven to twelve miles. I have selected these hospitals because I am personally acquainted with all of them, and have been officially connected with the Alcester and Evesham Hospitals since their establishment in 1875 and 1887 respectively. The majority of the cases removed to these hospitals were scarlet fever; the remainder were small-pox, diphtheria, and typhoid fever, there being comparatively few of the last named. It has been the custom in these districts for the medical adviser to state whether or not the individual patients are fit for removal and on that certificate the ambulance is sent. Thoroughly good ambulance arrangements and provision are in my opinion absolutely essential. It is by this means that it has been found practicable in London to transport cases of fever and small-pox (for distances equal to and even greater than those above mentioned) to the hospital and hospital ships of the Metropolitan Asylums Board. This has been done now for several years with safety to patients who are certified by their medical advisers to be fit for removal. In my opinion the powers conferred on county councils by Sections 6, 7, 8, and 9 of the Isolation Hospitals Act, 1893, should be utilised in rural and small urban districts to their fullest extent, inasmuch as the constitution of hospital districts including extended areas is generally conducive to efficiency as well as economy. Sections 6, 7, 8, and 9 of the Isolation Hospitals Act just referred to read as follows, viz. :—

"6. The county council may direct an inquiry to be made by the medical officer of health of the county as to the necessity of an isolation hospital being established for the use of the inhabitants of any particular district in the county, and in the event of such medical officer reporting that such an hospital ought to be established for the use of the inhabitants of a district, may take the same proceedings in all respects for the establishment of such hospital as if a petition had been presented by a local authority for the establishment of an isolation hospital for the district named in the report of such medical officer of health.

"7. The county council shall conduct the local inquiry into the necessity for the establishment of an isolation hospital, and as to the proper site for the hospital and the district for which it is to be established (in this Act called the hospital district), by a committee consisting of such number of their members either with or without the addition of such other persons or in such a manner as the council think expedient. All expenses properly incurred by any such committee shall be paid as hereinafter directed. The local inquiry shall be held subject to such regulations and otherwise as the council think fit. Due notice of the time and place at which any inquiry is to be held by the county council shall be given in such manner as the county council may think the best adapted to inform any persons interested, and such persons may attend and state their case before the members appointed to conduct such inquiry.

"8. (1) Every hospital district constituted under this Act shall consist of a single local area or two or more local areas as defined by

¹ A paper read at the Midland Branch of the Society of Medical Officers of Health on Jan. 3rd, 1895.

this Act. (2) The county council may vary any proposed hospital district by adding to it or subtracting from it any local area. A local area which is already provided with such isolation hospital accommodation as may, in the opinion of the county council, be sufficient for the reasonable exigencies of such area shall not without the assent of the local authority of such area testified by a resolution of such authority be included in the hospital district under this Act. (3) If any local authority having jurisdiction within any part of the proposed hospital district object to the formation of such a district or to the addition or subtraction thereto or therefrom of any local area within their jurisdiction, such authority may at any time within three months from the date of the order appeal to the Local Government Board, and the decision of such Board shall be conclusive.

"9. On conclusion of a local inquiry by the county council as to the necessity for the establishment of an isolation hospital, the county council shall make an order either dismissing the petition or constituting a hospital district and directing an isolation hospital for such district to be established. Provided that the county council shall not take steps for the constitution of a hospital district for one or more contributory places forming a portion of a rural sanitary district within the jurisdiction of the county council, or for one local area, unless the sanitary authority of such place or places or area assent to the application or are proved to the satisfaction of the county council to be unable or unwilling to make suitable hospital accommodation for such place, places, or area."

The county council of Worcestershire, after holding an inquiry by a committee of three of its members, one of whom was Sir Douglas Galton, K.C.B., have recently issued an Order (Section 9) grouping six sanitary districts (four urban and two rural), which collectively include an area of 104,973 statute acres and a population of 54,379. The following table gives the area and population of these districts.

TABLE II.

District.	Area in statute acres.	Population.
Bromsgrove country urban district ...	10,593	5,072
Bromsgrove town urban district ...	1,061	7,934
Redditch urban district ...	888	11,295
Droitwich urban district ...	1,705	4,021
Droitwich rural district ...	52,496	14,221
Bromsgrove rural district ...	38,227	11,836
Totals ...	104,973	54,379

The populous parts of this hospital district are for the most part situated to the centre of this area; but, on the other hand, there are two villages of considerable size which will be about twelve miles from the hospital. I propose, for the convenience of the medical officers and friends of the patients, that telephonic communication should be established between the hospital and the offices of the respective constituent authorities. By grouping these districts in this way I was able to show that considerable economy in construction and maintenance would be effected, as well as efficiency promoted, compared with any attempt on the part of the district councils interested to act independently. In conclusion, therefore, I submit that in most rural and small urban districts "grouping" of such areas for hospital purposes is desirable both for financial and other reasons. Furthermore, my experience—which I have recently learnt is corroborated by that of several medical officers of note—induces me to affirm that such a hospital district may often advantageously include a circle having a radius of eleven to twelve miles from the hospital as its centre, provided that the locality be non-mountainous, the highways well kept, the hospital accessible, and that thoroughly good ambulance arrangements are made.

Worcester.

A CASE OF DIPHTHERIA SUCCESSFULLY TREATED BY INSUFFLATIONS AND TABLOIDS OF PURE SULPHITE OF MAGNESIUM.

By BROWNLOW R. MARTIN, M.B. DUBL.

THE following case, which presents many points of interest, seems worthy of record in the columns of THE LANCET. On Wednesday, Jan. 16th, 1895, I was called in consultation by my friend, Dr. F. F. Moore of Mill-hill-park, to see a girl five years of age. On the previous Sunday, Jan. 13th, Dr. Moore saw this child for the first time, and then found a

slight membranous patch on one tonsil, the temperature being 102° F. As this patch continued to increase and spread he, suspecting diphtheria, asked me to visit with him. On our arrival on the afternoon of the 16th the case presented the following appearance. The tonsils, soft palate, uvula, and pharynx were thickly coated with leathery membrane, leaving no doubt in my mind that the surmise was correct. In order to make sure I removed some of the exudation with a sterilised swab and with it inoculated a tube of sterilised blood serum obtained from the Clinical Research Association, and handed it to the patient's father to transmit by post to that society for examination by their experts. I then freely insufflated the throat with pure magnesium sulphite, and Dr. Moore kindly did so three or four times daily, and between whiles the tabloids were administered. The result of bacteriological examination was as follows:—"The culture shows large numbers of typical colonies of diphtheritic growth. Microscopic examination of the culture shows the colonies to consist of almost pure bacillus diphtheriae; a few streptococci are associated with the bacillus." On visiting again with Dr. Moore on Friday, the 18th, the membrane had completely disappeared with the exception of a small patch not so large as a threepenny piece on one tonsil, and when I visited with him on Sunday, the 20th, every trace of membrane was completely gone. The points to which I would call attention are: 1. As to the child, she was thin, delicate, and anæmic, not in any way gifted with a constitution calculated to inspire one with much confidence as to her inherent ability to successfully combat an enervating disease. 2. Not only were the bacilli of pure diphtheria present, but also some streptococci. 3. No medicine of any kind was administered internally except the tabloids, the treatment relied on being the insufflations. 4. The rapidity of the cure. 5. The complete absence of any sequelæ, which, up to this day, the thirtieth, have not appeared.

CHARING-CROSS HOSPITAL.

ENUCLEATION OF HYDATID CYST OF LIVER; RECOVERY;
REMARKS.

(Under the care of Mr. JOHN H. MORGAN.)

THE treatment of hydatid cysts of the liver has, like most other diseases of that organ amenable to surgical operation, undergone various changes during the past few years. With reference to tapping of such cysts it is interesting to get definite records of cases, and these are supplied by the statistics of Dr. Davies Thomas¹—411 cases treated with the following result: 163 were reported cured, in 92 the operation failed to cure, in 68 relief was afforded, in 5 no relief was afforded, in 10 the result was unknown, and 73 died. Better results have been obtained by direct incision and drainage, the cyst being stitched to the margins of the abdominal wound. This method has been replaced by the removal of the mother cyst at the time of incision. Dr. J. C. Verco,² in a paper on the treatment of hydatid cysts, stated that he has never seen a surgeon in South Australia leave the membranes in a hydatid cavity after it had been opened by incision. He also pointed out that the fear of hæmorrhage should not deter the surgeon, as there is no organic connexion between the cyst wall and the cavity in which it lies.

The patient, a woman aged thirty-eight years, had noticed for four years a fullness unaccompanied by pain in the right hypochondrium. Except for an attack of dysentery in childhood, she had enjoyed good health and had never had jaundice. She had lived in England all her life. On Aug. 9th,

¹ Sajous' *Annals of the Universal Medical Sciences*, 1894, vol. iii. cap. 5.

² *Ibid.*, 1892, vol. iii., cap. 25.

1894, she had consulted her medical attendant for an attack of diarrhoea and vomiting, and he, finding the enlargement of the liver, advised her to go to the hospital, where she was admitted on Aug. 16th, under the charge of Dr. Bruce. She was a well-nourished, slightly anæmic woman, and on examination of the abdomen there was found a tumour lying to the right of the umbilicus and extending downwards into the right lumbar region and upwards into the right hypochondriac region. Its upper part sank under the costal margin, so that its extent could not be ascertained; its lower border was a few inches above the symphysis pubis; externally it extended with a convex margin towards the kidney, while internally it reached to the umbilicus. But for a dull heavy weight in the right side, the patient suffered no pain, and she had not lost flesh. She remained for some time under the observation of Dr. Bruce; but as no improvement took place a consultation was held, and Mr. Morgan inserted a trocar, and a very small quantity of clear fluid was withdrawn, which, when examined under the microscope, gave evidence which confirmed the diagnosis of hydatid cyst. It was decided to expose the tumour, and, if possible, to enucleate it. On Jan. 19th, 1895 a vertical incision was made over the tumour in the right linea semilunaris, at first two inches and a half long, but afterwards prolonged upwards to the costal margin and downwards to the extent of five inches. The parietes having been cut through and hæmorrhage arrested the peritoneum was snicked and divided with scissors. The tumour was at once seen, presenting a white shiny opaque wall, free from adhesions on its anterior surface and below. The tissue of the liver spread over a small area in front and projected on both its upper and lower surfaces. The tumour felt extremely hard and firm, and but for the microscopic examination of the fluid previously withdrawn might easily have been taken for a malignant growth, the surface looking greyish-yellow, with numerous superficial vessels. A trocar was inserted, but not more than half a drachm of clear greyish-yellow limpid fluid was withdrawn. At a later stage this proceeding was repeated in the hope of reducing the size of the tumour, but with no better result. The abdominal wound was packed below and on either side with broad, flat sponges, which were frequently changed during the remainder of the operation. The cyst was then cautiously and gradually enucleated. It was free from attachment to the surrounding structures in front, below, and on either side, but above and behind it was intimately connected with the liver substance, and was separated by the fingers with the greatest difficulty. On the outer and lower surface of the tumour there was seen a second prominent, tense, cyst-like swelling as large as a plum and closely connected with the larger tumour, of which it at first appeared to be a prolongation, but after the cyst wall had been slit up to admit the finger this second tumour was found to have no connexion with its interior, and steps were taken to strip it from the larger cyst, to which it was closely adherent. As it came away it was seen to be pear-shaped, with the apex upwards and passing to the hilum of the liver, and was recognised as the moderately distended gall-bladder. During this proceeding several vessels were torn. It being found impossible to separate the tumour from its connexions as it stood, it was opened freely along its anterior surface. No fluid escaped, but at once there poured out hundreds of daughter cysts of all sizes, from that of a pin's head to that of a large cherry, nearly filling a pint bowl. The cyst was emptied with a scoop, care being taken that none of the daughter cysts entered the peritoneum. The cyst wall was then teased away entire, exposing a raw surface of the liver and upper portion of the gall-bladder. Several vessels deep down in the cavity were ligatured, and hot boracic lotion was applied to the wounded surface. The bleeding was not formidable and ceased when hot dry sponges were applied. The wound in the abdominal wall was closed by a number of silk sutures passed through all the layers and including the peritoneum, and sal alembroth gauze and wool and an ovariectomy binder were applied. The operation lasted about an hour. The cyst was nearly as large as two closed fists; the wall was thick and tough and bore considerable traction with strong ovariectomy forceps without giving way. A portion of the outer wall remained attached to the liver, and was removed with scissors. The inner surface was smooth and partly covered by a lining of yellowish gelatinous material, which easily stripped off. The patient slept fairly well after a dose of morphia. There was some vomiting for the first forty-eight

hours. Only hot water was given by the mouth, and nutrient enemata were administered per rectum. The temperature did not rise above 99.4° F. The stitches were removed on the tenth day, and she left the hospital perfectly recovered at the end of three weeks.

Remarks by Mr. MORGAN.—The plan which was followed in the above case is a further development of that advocated by Mr. Lawson Tait, and is that which finds most favour with Australian surgeons, whose opportunities for gaining experience in this class of disease are so much more frequent than in this country. No doubt the case described was admirably suited to the plan which was followed, and it would not be possible in many cases to act on similar lines. In a paper by Mr. Wallis in the St. Bartholomew's Hospital Reports there is pointed out the danger of simple puncture, which is often followed by fatal results, which are ascribed as being due either to shock or to some active poison in the hydatid fluid which takes immediate action on the heart or respiration. In Mr. Lawson Tait's operation the sac, having been exposed, is incised and carefully evacuated; the edges of the incised sac are then stitched to the skin, and its cavity is washed out with some non-irritating antiseptic fluid and then sponged dry, a drainage-tube being inserted if thought necessary. This plan has been most successful in the hands of Australian surgeons; but the further development of this method as described in the above case—namely, the complete evacuation of the cyst and the enucleation of the sac where possible of accomplishment—must necessarily be a more satisfactory and radical measure. With proper precautions and good assistance the only danger to be apprehended is from hæmorrhage, and this can to a large extent be discounted by modern methods and the exercise of great care and patience. In the present instance it was never formidable and was soon arrested. It may be noticed that no drainage-tube was used, and that the site of the operation was marked only by a short linear scar, which was found to be firmly healed in ten days. The proximity and intimate connexion of the gall-bladder to the wall of the cyst might have led to serious complications if it had not been recognised. No harm seems to have followed the manipulation which was necessary to separate the adhesions between the two surfaces.

TORBAY HOSPITAL, TORQUAY.

WOUND OF KNEE-JOINT, FOLLOWED BY SUPPURATION;
RECOVERY.

(Under the care of Mr. F. T. THISTLE.)

THERE are few cases which call for the exercise of more care and skill on the part of the house surgeon to a hospital than those of suppuration in a large joint such as the knee. They require such unremitting attention and rigid application of certain definite rules of treatment that it is not usually possible for the visiting surgeon himself to fully give them the attention necessary. Even at the present day, when our results are so much better than they were twenty years ago, a suppurating knee-joint is a source of considerable anxiety amidst the best surroundings, and when a useful limb is obtained it is fit subject for congratulation. There are three things which are essential in such cases—adequate drainage, immobilisation of the limb, and an efficient dressing. It would, however, not be right to omit to remind our readers of the credit due to the careful nursing required, more especially in an adult case. In this patient the careful antiseptic treatment with drainage prevented suppuration in the first instance; a secondary suppuration the result of injury is unusual. For the notes of this case we are indebted to Mr. Arthur Watson, house surgeon.

A strong, well-developed man thirty years of age was admitted into the Torbay Hospital on May 19th, 1892. The patient whilst working at a quarry had been knocked over by a mass of rock and had fallen some fifteen or twenty feet, his left knee striking against a sharp point of rock. On admission to hospital a jagged-looking wound one inch in length could be seen on the outer side of the left knee and about two inches from the lower and outer margin of the patella. A copious sero-sanguineous discharge was oozing from the wound and could be pressed out from the under surface and side of the knee-joint. On introducing the

finger into the wound it was found that the knee-joint had been opened, the lower border and under surface of the patella could be felt, and in the same way part of the articular surfaces of the tibia and femur. It was decided to enlarge the primary wound at once, and to make a counter-opening on the inner side of the joint. This was accordingly done, and a drainage-tube passed through and the joint well irrigated with perchloride of mercury lotion (1 in 2000). The limb was fixed on a back splint and a dressing of blue wool, white wool, and carbolic gauze applied. The patient did well and had only a very slight rise of temperature at night, the temperature falling to normal on the eighth day. There was only a slight serous discharge from the wounds for the first four days. The joint was irrigated twice daily with mercurial lotion. One half of the drainage-tube was removed on the eighth day and the remainder five days later. The patient was discharged from the hospital on June 1st with the limb in plaster-of-Paris, and was told to keep the foot off the ground and to walk with the aid of crutches. He came to the hospital several times, and although the left knee-joint was somewhat larger than the right there was no increased heat or pain. On the morning of July 18th he was brought up to the hospital complaining of great pain in the knee. He stated that the night before he tried to walk across his bedroom without crutches and had tripped and fallen heavily on the left leg; this caused intense pain and he could not sleep. On examination the knee was found to be greatly swollen and tense; fluctuation could be obtained; it was extremely painful and tender; the skin round the joint was reddened, and the temperature was 102.2° F. He had had no rigors. He was readmitted to hospital, and on the afternoon of the same day a long hypodermic needle was thrust into the joint, and a small quantity of thin pus withdrawn. The patient was then anaesthetised, and an incision made on each side of the joint, but more posteriorly than the first incisions. The joint was drained as before, and irrigated twice a day. Hot carbolic fomentations were applied every three hours, and he was given a sleeping draught at bedtime. The temperature continued raised for some weeks, being about 101° in the evening, and falling to 99° or normal in the morning. The patient began to lose ground, and it was feared that amputation would be the only resource left. The discharge, however, lessened, and the temperature began to fall. On Aug. 20th the following note was made: "The patient has much improved during the last fortnight; there is now a little serous discharge from the wounds. The knee, although still swollen, is not painful or tender to touch. His temperature has been normal since the 7th; he takes his food well and sleeps well." The patient continued to improve, and left the hospital on Oct. 31st (fifteen weeks since admission). He has continued well ever since, and has for the last few months been following his usual work. The leg is straight; there is very little movement in the joint, but he can do a good day's work and walk long distances without pain or fatigue.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Researches on the Pneumococcus, with especial reference to Immunity.—Notes on the Bacteriology and Pathological Chemistry of Pneumonia.

An ordinary meeting of this society was held on Feb. 5th, Dr. PAVY, F.R.S., President, being in the chair.

Dr. WASHBOURN read a paper on the Pneumococcus, with especial reference to Immunity. He stated that Friedlander's pneumococcus was only of accidental occurrence, and that the pneumococcus of Salamon and Fraenkel was the real cause of the disease. The pathogenic properties of the pneumococcus in the human subject were mentioned. In addition to causing acute lobar pneumonia it was the cause of some cases of lobular pneumonia, other bacteria, especially streptococci, being the frequent cause of the latter disease. The peculiarities of the cultivation of the pneumococci were described. He considered the reaction of the medium and the temperature the most important factors. The cultivations rapidly lost their vitality; exceptions, however, had from time to time been recorded. In one case he found a broth cultivation alive and virulent twenty-three days, and in one an

agar cultivation alive and virulent sixty-four days, after being sown. This was possibly due to a spore formation, as believed by Emmerich, whose experiments were described. The short vitality of the pneumococcus rendered investigation difficult. The method of Arkharow and Foa of preserving the vitality in sealed tubes was described. Dr. Washbourn himself had adopted a method used by Pfeiffer for cultivating the pneumococcus on the surface of agar covered with blood. Experiments were quoted to show that on this medium it retained its vitality and virulence for as long as fifty days. Fraenkel and Reiche independently used the same method. The pathogenic effect produced by inoculation of the pneumococcus in different animals was described. Special mention was made of Dr. Washbourn's own extensive experience in the case of rabbits. Intra-peritoneal and subcutaneous inoculation were both employed. After the former peritonitis usually ensued; sometimes with very virulent cultivations no peritonitis was noticed, although the animals died from general infection. Sometimes an animal died from marasmus a long time after inoculation. No cocci are then found in the blood, but in some cases there was a parenchymatous nephritis. The course of the fever and the occurrence of cocci in the blood after inoculation were described in detail. It was not until the temperature began to fall that the blood became crowded with cocci. Of the various methods of producing immunity Dr. Washbourn had generally used that of G. and F. Klemperer by previous injection with heated broth cultivation. The immunity did not occur until twenty days after injection, and disappeared after the thirty-first. The experiments of others with the blood serum of immune rabbits were described, and Dr. Washbourn mentioned his own experiments. He quoted a number of experiments showing that the blood serum when injected with virulent cultivations was protective. In other cases the serum was not protective, and this was due either to the rabbits not being perfectly immune or to the fact that the serum was removed at the wrong date. The experiments of Klemperer with the serum of patients recovering from the effects of pneumonia were described. He (Dr. Washbourn) made but a few experiments and was only able to prolong the life of the inoculated rabbits. The serum removed by a blister from patients in the acute stage of the disease, injected either simultaneously with or previously to inoculation, exerted a deleterious effect and caused death earlier than in the control experiment.

Dr. A. E. WRIGHT read a paper on the Bacteriology and Pathological Chemistry of Pneumonia. "Diseases," he said, "which are due to bacterial infections may be classed into three great categories; they may be either 'septicæmias,' 'local inflammatory processes,' or 'intoxication processes.' In the case of septicæmias the bacteria are found free in the blood when the disease is at its height; in the case of local inflammatory processes the bacteria are constantly present in the inflamed tissues, but they do not necessarily invade the blood; and in the case of intoxication processes the bacteria elaborate their poisons only upon the inner or outer surface of the body, but the bacteria themselves do not invade the tissues. Now croupous pneumonia is primarily a local inflammatory process, and the lesions which characterise it are the result of an acute phagocytic reaction of the organism in response to a bacterial infection of the lungs. The infecting bacteria are generally the pneumococci of Fraenkel. Now the emigration of white blood-corpuscles into the alveoli of the lungs is entirely comparable with the emigration of white blood-corpuscles into the subcutaneous tissues, which constitutes an ordinary abscess. The white blood-corpuscles which emigrate are in both cases polynuclear white blood-corpuscles, and the subcutaneous abscess, equally with the pneumonia, may be the result of a pneumococcal infection. There are, however, important clinical differences between an attack of croupous pneumonia and a subcutaneous abscess. We need not refer to the obvious differences which result from the fact that the emigration of white blood-corpuscles in pneumonia directly interferes with the aeration of the blood. Nor need we refer to the fact that the emigration of white blood-corpuscles in pneumonia is a much more acute process. But we may turn our attention to the more important clinical difference which consists in the fact that pneumonia runs a definite course and terminates by crisis. The crisis which terminates an attack of pneumonia is very similar to the crisis which we meet with in connexion with spirillum fever, and spirillum fever is a typical septicæmic infection, and if we could succeed in understanding what occurred in the organism in the crisis of spirillum fever we

should probably not find it difficult to understand what takes place in the organism in the crisis of what we may now provisionally call 'pneumococcal fever.' I have therefore searched the admirable monograph of Vandike Carter for any data that appeared to throw a light upon this question of the pathology of the crisis. We learn the following facts from Carter. When spirillum fever is at its height we have an enormous proliferation of white corpuscles in the blood. We have also a number of free spirilla in the blood at the height of the fever. When the crisis supervenes the white blood-corpuscles diminish rapidly in the blood, and *pari passu* with their diminution we have a complete disappearance of spirilla from the blood. This diminution of white corpuscles and disappearance of spirilla are in nearly all cases associated with an excessive turgidity, and tumefaction, and tenderness of the spleen or liver. Now this triple phenomenon of a diminution of the white corpuscles, a disappearance of the bacteria from the blood, and the tumefaction of the internal organs, especially the spleen and liver, can be experimentally produced. We need only, as Werigo has shown, inject bacteria or particulate matter of any kind, such as carmine grains, into the blood, and we shall immediately produce our triple phenomenon. Almost all the polynuclear white corpuscles disappear from the blood in the course of the next few minutes, and on killing the animal we find the bacteria or particles we have injected in the internal organs, chiefly in the spleen and liver, and along with them we find our polynuclear white corpuscles. And we further find that many of our particles or bacteria are lodged in the interior of our polynuclear white corpuscles; and we thus see that the disappearance of white corpuscles from the circulating blood, the disappearance of the bacteria, and the tumefaction of the internal organs are all manifestations of a phagocytic reaction, which eliminates these intrusive elements from the circulating blood. We have now to apply these facts to the pneumonic crisis. During the height of the fever we have an enormous increase of the circulating blood-corpuscles, especially of the polynuclear white corpuscles. When the crisis occurs we have a very rapid fall in their number. In the first of a series of cases recorded by V. Limbeck the white corpuscles in the circulating blood decreased from 22,000 to 6400 when the crisis occurred. And if our hypothesis is true we should find that this diminution of white corpuscles which goes hand in hand with the critical fall of temperature was associated with a process of phagocytosis and with an elimination of pneumococci from the blood. We may now pass on to the pathological chemistry of pneumonia, and I have very little that is new to add to what I published three years ago in a lecture¹ in which I gave an account of the research work I was privileged to do at the laboratories of the conjoint Colleges. I desire, however, to repeat myself, for what I had occasion to state in that lecture appears to me to be confirmed by my subsequent researches, and I believe that it is the key to the understanding of many of the phenomena of pneumonia. We shall suppose that the pneumonic fever has terminated with the crisis and that it is over, and we shall suppose also that the local inflammatory process has also come to an end. Our patient is, however, not well yet, and it is not with him merely a question of recovering the strength he has lost. He has not simply to convalesce. He has also to undo all that the local inflammatory process has done. He has to reabsorb into his system and then to excrete substances which are contained in the enormous mass of white blood-corpuscles which is filling up the alveoli of his lungs; and as the albuminous substance of these white blood-corpuscles has to be absorbed into his blood it concerns us to study what this albuminous substance is and what effect it will have upon his blood. The answer to these questions can be given in a single sentence. Almost the entire substance of the white blood-corpuscle consists of a nucleo-albumen, and this nucleo-albumen is identical with the nucleo-albumen originally prepared by Wooldridge from the white blood-corpuscles of the thymus gland. It is hardly necessary to say that the injection of this albuminous substance was shown by Wooldridge to be followed by intravascular thrombosis; and it is only necessary to take a pneumonic lung and to make an extract with a solution whose alkalinity is comparable to that of the blood plasma, and to inject this solution into the blood of a dog, in order to kill the animal instantaneously with intravascular thrombosis. On the other hand, it is possible that the absorption of the nucleo-albumen from the lungs may take place so gradually

that its absorption may present no analogy with the sudden injection of nucleo-albumen into the blood in Wooldridge's experiment. We should then have nothing to fear in the direction of intravascular thrombosis. We should have to deal instead with the symptoms which result from a slow injection of nucleo-albumen into the blood. And these symptoms are a diminution of blood coagulability, which is analogous to the diminution of coagulability which results in animals from an injection of peptone; such a diminution of blood coagulability might be accompanied in man, as it is in the dog injected with peptone, with diarrhoea. Perhaps many of the critical diarrhoeas may be explicable in this manner."—Dr. RUFFER asked whether the serum of animals dead from pneumonia exhibited either antitoxic or curative power. There was another poison present in the juices of animals dead from diphtheria—namely, that producing paralysis; and he asked whether any similar observation had been made in pneumonia.—Dr. WASHBOURN, in reply, said that neither antitoxic nor curative power appeared to reside in the serum of pneumonic animals, and there were no late developments comparable to the paralytic seizures in diphtheria.

OPHTHALMOLOGICAL SOCIETY.

Two Cases of Diphtheritic Conjunctivitis treated by Klein's Antitoxin—Removal of the Lens in High Myopia, with a Case of — 25 D.—Eyesight and the Public Services.—Exhibition of Specimens.

AN ordinary meeting of this society was held on Jan. 31st. Dr. D. ARGYLL ROBERTSON, F.R.S.E., President, being in the chair.

Mr. W. H. JESSOP described two cases of Diphtheritic Conjunctivitis treated by Klein's Antitoxin. The first case was that of a boy aged nineteen months who had membrane on the upper and lower palpebral conjunctiva of the left eye, and a patch of membrane on the left side of the uvula; one lymphatic gland over the parotid was enlarged, and there was albumen in the urine. Three injections of Klein's antitoxin were given, one and a half drachm in all; the membrane disappeared in five days, and was not followed by conjunctivitis or other conjunctival change. There was no local treatment except distilled water. The second case was that of a male child eight months old. There was membrane on the palpebral conjunctiva of both eyes; the parotid lymphatic glands were enlarged; there was a muco-purulent discharge from the nose. Two injections of Klein's antitoxin, one drachm in all, were given, but there was no local treatment. The membrane disappeared in four days.—Dr. HAYWARD had examined the membrane in both cases and found large quantities of Löffler's bacillus. The membrane was well marked in both cases and only affected the palpebral conjunctiva.—The PRESIDENT inquired whether any paralysis had followed, as in diphtheria of the fauces.—Dr. HABERSHON asked the date of appearance of the membrane, as antitoxin injections were of little avail after forty-eight hours from its first development.—Mr. MACKINLAY referred to Mr. Tweedy's method of treatment by quinine and the good results obtained.—Mr. JESSOP, in reply, said it was still too early to look for any paralysis. The membrane was present when the patients presented themselves, and injections were employed at once. He could not say how long it might have existed. He doubted whether the cases quoted by Mr. Mackinlay were truly diphtheritic. As a rule, these cases did not recover without serious injury to the eye, and were usually complicated by purulent ophthalmia. His own cases were the first in which the new method of treatment was employed, and recovery so far had been perfect and had not been followed by any discharge.

Mr. C. WRAY read a paper on Removal of the Lens in High Myopia, with a Case of — 25 D. He thought that the operation was not applicable in the case of children with less than 10 D or in adults with less than 12 D of myopia. The objects of the operation were three in number: (a) to prevent detached retina; (b) to arrest or prevent retino-choroidal changes; and (c) to enable patients with the highest grades of myopia to work at reading distance if unable to do so. He presented statistics of myopia of 123 patients with 246 eyes; 38 cases, including 3 cases of detached retina, had vision less than $\frac{1}{16}$ in one eye, whilst 10 had vision less than $\frac{1}{16}$ in both eyes. His figures, he considered, admitted of three deductions: that the vision

was invariably less in the fourth decade than in the third; that retinal detachment was less to be feared than the changes in the retina and choroid; and that it was not necessary to regard every myope of 12 D and upwards as hopelessly drifting towards detached retina and blindness. He had seen a case of retinal detachment after the removal of a lens in a case of myopia of 30 D, and considered detachment comparatively frequent after operation. He pointed out that in myopia of low degree, associated with zonular cataract, the crescent is at times out of all proportion to the amount of myopia; and the presumption was that this was due to amblyopia, and on this conviction it was a common thing to remove zonulars when the patients could see $\frac{5}{6}$ and J 4, but he regretted that hospital reports did not furnish the subsequent history of these cases. As regarded the prevention of changes in the choroid and retina, the only case that would appear to bear upon the point was Meyer's, in which, after the removal of a lamellar cataract from a myope, the fundus changes were said to have progressed, and, judging from the statistics at his (Mr. Wray's) disposal, more rapidly than they would have done in all probability in the natural course of events. The point on which there was unanimity was that the patients were able to work much better after the operation, and some were enabled to follow vocations which had previously been impossible.—Mr. SPENCER WATSON commented upon the novelty of operation for this condition. He said he would himself hesitate to undertake it, not seeing how removal of the lens could relieve the progressive changes in high myopia. He had once removed a lens with its capsule for cataract in the subject of a high degree of myopia, and there had been some loss of vitreous, but the patient recovered well and with improved vision.—Mr. MARSHALL, Mr. HODGES, Dr. ROCKLIFFE, and Mr. RIDLEY mentioned cases in which interference had proved unavailing.—Mr. DOYNE did not think that loss of the lens would improve vision in a myopic and amblyopic eye.—Mr. LANG said he had operated for black cataract in an eye with 23 D myopia. Vision was improved from $\frac{1}{60}$ to $\frac{1}{30}$, but after some months the retina became detached. The same thing occurred in the other eye, so he did not think it could be attributed to the operation. On the whole, his experience was not favourable.—Mr. WRAY, in reply, said the age at which the operation was performed was of great importance. Cases showing 10 D myopia between the second and fourth decades underwent marked deterioration later. All those alluded to in the paper were amblyopic eyes with crescents. He thought the longer it was postponed the worse it would be. The operation would involve removing immature cataracts at the most dangerous age, and speakers had not mentioned the ages of their unsatisfactory cases.

Mr. MACKAY (Edinburgh) read a paper on Eyesight and the Public Services. His object was to express an acknowledgment and to elicit an opinion. The acknowledgment was that the recognition of the importance of good eyesight in the public services was due to the action of members of this society. The opinion to be elicited was whether the visual examinations were conducted in a satisfactory manner. He gave a short summary of the history of visual examination. In the public services coming to present facts, it would be found that there was a great difference between the method of fixing the standard recommended by this society and that generally regarded as sufficient by laymen or those not engaged in ophthalmic practice. The chief difference was that the one included an estimation of the refraction of the eye, the other did not; the result of this was that some candidates might be passed with a latent error so great that a time might come when their vision without glasses might fall below the standard, and they might have a difficulty in continuing their duty. This neglect of refraction was costly to the employer and a cause of hardship to the employed.—Mr. DOYNE considered the published instructions as to examination of vision were of no value whatever except for the navy.—Mr. MCHARDY said that for the Royal Navy full normal acuity of vision was required, no latitude whatever being allowed. He thought there was intense hardship in applying some tests of vision, not of refraction, to boys of twelve years after prolonged application, when there was sometimes temporary spasm of accommodation, which excluded the most studious, full acuity of vision being attained later. Cases of myopia were passed, refraction not being tested. Among the engineers the physical examination was held after the competitive one, which was regarded as a hardship in the navy. He strongly advocated the refraction test.—Fleet-Surgeon PRESTON said that in applying the tests there

were two standards. In the executive, including the fighting men and engineers, the highest standard of vision was required; while in the case of the civil department, including surgeons, chaplains, and paymasters, much more latitude was allowed. In the navy it was required that a man should read all the letters in the test types, and not merely two or three in a line. Cases of hypermetropia and astigmatism were rejected. Colour vision was adequately tested by coloured tinting, Holmgren's wools, and tinted glasses. An estimation of the refraction in each case would require a staff of specialists, and there was no money provided for such a purpose. He admitted there was some hardship in the physical examination being held after the competitive one. In answer to Mr. Bickerton (Liverpool), he said perfect colour vision was required with either eye. The earliest rules were published in 1864.—Mr. BICKERTON cited the case of the *Vanguard*, which was lost through slowing down in a fog—owing to one "look-out" man with defective sight out of five giving notice of a vessel ahead seen by no one else. This led to the ship being run down by the *Iron Duke*, which was following.—The usual time of the meeting having expired, a prolongation was proposed by Mr. PRIESTLEY SMITH, and seconded by Mr. STEPHENSON.—Mr. PRIESTLEY SMITH said there was a want of correspondence between the idealists and practicalists. Normal vision was represented by the power to discern $\frac{5}{6}$ in Snellen's types in a good light. The expressions used in the pamphlet that every candidate should be emmetropic ought to be crossed out if the refraction was not examined.—Mr. CRITCHETT said he fully endorsed these statements. A uniform bright light was essential.—Mr. LANG said he knew of one naval surgeon who tested his cases under a mydriatic, which was very much more satisfactory.—Mr. MACKAY replied.

Dr. STEPHEN MACKENZIE proposed the following resolution, which was seconded by Mr. JULER:—

"1. That in the opinion of this society no examination of eyesight is complete or satisfactory which depends mainly upon an examination of the form vision by means of test types and dots and omits consideration of the refraction of the eye.

"2. That this society hereby appoint the President of the society (Dr. ARGYLL ROBERTSON), Mr. Power, Mr. Nettleship, Mr. Lawson, Mr. Couper, Dr. Frazer, and Mr. Hartridge to accompany the deputation of the British Medical Association to the Board of Trade on Feb. 1st at 3 P.M. to give expression to the foregoing resolution."

The following card specimens were shown:—

Messrs. HODGE and RIDLEY: Intraocular Melanotic Sarcoma with Peculiar Characteristics.

Mr. LAWFOORD: Unusual Arrangement of the Retinal Vessels.

Dr. ARGYLL ROBERTSON: A specimen of Filaria Loa.

Mr. MACCUS GUNN: (1) Peculiar Lenticular Changes following Old Injury of Eyeball; (2) Prolonged Hypermetropic Congestion of Optic Discs closely simulating Papillitis.

Mr. E. CLARKE: A case of Pulsating Exophthalmos.

Dr. J. HAYWARD: Microscopical Specimens and Cultivations of Löffler's Bacillus.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Casual Cow-pox.—Intestinal Affections requiring Surgical Treatment.

A MEETING of this society was held on Feb. 1st, the President, Dr. R. BANNING, being in the chair.

Mr. BUCKNILL related a case of Casual Cow-pox which occurred in a man thirty-four years of age, who noticed a papule on the flexor surface of his left forearm two days after milking two cows; other spots followed and the pocks presented a most typical appearance. The vesicles contained clear fluid. During the first few days after the inoculation the patient complained of severe headache and general malaise; there was a deposit of urates in his urine and swelling and tenderness of the axillary glands. One of the cows was found to be suffering from bovine variola, and presented a number of dried-up pustules on the teats. All efforts to trace the origin of the disease proved abortive. The patient had four excellent marks of primary vaccination, and was revaccinated after this disease, but, as was fully expected, without the slightest result.—The President and Mr. Wood took part in the discussion.

Mr. KEETLEY then read a paper on some Intestinal Affections requiring Surgical Treatment. After referring to

twenty cases in which he had operated he remarked that physicians usually did not call in a surgeon except as a last chance, and that this delay was accountable for the high mortality of such cases. In his opinion the general attitude of patients towards operations was now changed, so that there was seldom any difficulty in obtaining their consent to laparotomy. He specially deprecated the administration of opium before a certain diagnosis had been arrived at, and recommended the administration of chloroform to facilitate the diagnosis. He also pointed out the similar symptoms which cases of appendicitis presented to those of other conditions. With regard to intestinal tumour he attributed their late diagnosis to the practice of treating obscure abdominal symptoms without making a thorough examination. He then reviewed the various methods of performing intestinal anastomosis, and gave the preference to Maunsell's method. Finally, he related a successful case of removal of a tumour of the ileo-cæcal valve.—Mr. EDWARDS mentioned a case of excision of rectum by Kraske's method, in which he attempted to join the cut ends by means of Murphy's button. The anastomosis was not successful, but the patient made a good recovery. He pointed out how satisfactory was the prognosis in cases of excision of rectal cancer if the case was operated on sufficiently early.—Dr. CHAPMAN called to mind many obscure abdominal cases which had recovered without operation. He doubted whether it was any use to operate on cases of intestinal cancer on account of the risk of recurrence.—Mr. BIDWELL could not agree with Dr. Chapman, and referred to two cases of removal of intestinal cancer—one from the cæcum and the other from the sigmoid flexure—which were alive four and two years after the operation respectively. He considered that the hesitation which physicians showed in handing over obscure abdominal cases to a surgeon was due to the fear of death from peritonitis. He pointed out that there was very little risk of this, and referred to twenty-nine laparotomies which he had done, in none of which was there any peritonitis, although four deaths occurred from other causes. Finally, he agreed with Mr. Keetley in recommending Maunsell's method of intestinal anastomosis, and related a case where he had recently successfully resected five inches of small intestine by this method. For lateral anastomosis he recommended Halstead's method, and referred to two cases of gastro-jejunostomy which he had performed by that method.—Dr. ROBERTS related a case of tuberculous peritonitis in which, although an abscess formed and was allowed to burst, the patient recovered.—Dr. MAUNSELL described his method of anastomosis. He advised the use of a piece of sponge over which is passed a safety pin as an intestinal clamp.—Dr. KEETLEY replied.

LIVERPOOL MEDICAL INSTITUTION.

Glioma of the Retina.—Injury to the Internal Carotid Artery; Ligature of the Common Carotid; Recovery.—A Case of Acromegaly benefited by Treatment.—A Case of Anæsthetic Leprosy.—Successful Trephining for Meningeal Hemorrhage.—Pregnancy complicating Fibroid Tumour of the Body of the Uterus.

A MEETING of this society was held on Jan. 31st, Mr. CHAUNCEY PUZEY, President, being in the chair.

Mr. RICHARD WILLIAMS showed a child the subject of well-marked Glioma of the Right Retina. He intended to enucleate the eyeball on the following day.

Mr. DAMER HARRISON related a case where the Internal Carotid Artery was wounded by a sharp, dagger-like instrument close to its entrance into the skull. The common carotid artery was tied and the wound plugged daily with cyanide gauze. The patient made a good recovery.

Dr. CATON described an early case of Acromegaly occurring in a woman aged twenty-seven. Enlargement of the hands, feet, lower jaw, tongue, nose, and lower lip had taken place. She complained of headache, aching in the eyeballs, dimness of vision, and excessive lacrymation. Exophthalmos was present, with oedema round the eyes and greatly diminished visual fields, but no optic neuritis or temporal hemianopsia. The thyroid was small. The patient complained of pain in the right hypochondrium, coldness of the extremities, muscular feebleness, depression, and apathy. After three months' treatment by rest, tonics, and good food she appeared to be worse rather than better. About the beginning of November,

1894, three tablets, each containing two grains of pituitary body, were given daily. After this her condition showed much variability; sometimes she was much better. On Dec. 18th, in view of the analogy between acromegaly and myxœdema, thyroid tablets were alternated with pituitary tablets. From this time improvement was rapid; all pain, headache, and oedema disappeared. Vision became perfect, and the visual fields normal in extent. The hands and feet diminished in size, as did also the lower lip. Her facial expression changed, muscular strength increased, and she became as cheerful and active as she had been three years before. Lantern photographs of the patient were put on the screen, showing the very great improvement in the patient's appearance since taking the thyroid and pituitary tablets.

Mr. BANKS showed a young man on whom he had operated five years before for Swelling in the Ulnar Nerve. The man was of dark complexion, his mother being an Eurasian. At the time of the operation he complained of great loss of power in the right arm. There was a long cylindrical swelling of many inches of the ulnar nerve; sensation was lost over the area supplied by this nerve. The nerve was exposed and very carefully split lengthwise, and a long, pinkish core, looking like old blood-clot, was removed from its interior. On microscopical examination this substance was found to contain the bacilli of leprosy. The man speedily regained power over his arm, and the lost sensation returned. At present he could use one arm as well as the other.

Mr. DAMER HARRISON showed a man who had been successfully Trephined for Meningeal Hemorrhage.

Dr. T. B. GRIMSDALE read a paper on Pregnancy complicating Fibroid Tumour of the Body of the Uterus. Having made a general reference to the subject and considered the symptoms, diagnosis, and dangers of the condition, he related a case in which he had terminated pregnancy at the fourth month. He rapidly dilated the cervix with Hegar's dilators, and extracted the fetus and placenta at one sitting. The result was quite satisfactory, and there was no hæmorrhage at the time of the operation. In this case the fibroid was larger than an adult head, and the abdomen was as much distended as if the pregnancy had reached full term. Dr. Grimsdale discussed the various methods of treatment adopted in these cases, and suggested some lines on which treatment should be regulated. He thought that the plan he adopted in his case would be applicable to a considerable number of cases of this description.—Drs. BRIGGS, GEMMELL and IMLACH criticised the paper.

Reviews and Notices of Books.

A Handbook of the Diseases of the Eye and their Treatment. By HENRY R. SWANZY, A.M., M.B., Surgeon to the National Eye and Ear Infirmary, Dublin. Fifth edition with illustrations. pp. 582. Edited, under supervision of the author, by LOUIS WERNER, M.B. London: H. K. Lewis. 1895.

WE are glad to see this serviceable and well-written manual has attained its fifth edition. The author has secured the services of an able coadjutor in Dr. Louis Werner, who has conscientiously performed his task of editing the work. The volume has been increased by about one-tenth of its former size, and various additions and modifications have been made, amongst which may be mentioned an account of the astigmatometer and its use, of the effects of electric light on the eyes, of scintillating scotoma, of ophthalmia nodosa, and of enophthalmos. The articles on tubercle of the iris and tumours of the optic nerve have been rewritten, and some of the chapters have been revised and extended. Dr. Swanzy is one of the most vigorous advocates of the method of operating for cataract in which the linear operation is combined with a small iridectomy, and his success has been such as to justify his teaching. He states that in 200 consecutive extractions he has only had two cases in which prolapse of the iris occurred with incarceration. He adopts a proceeding after the delivery of the lens which he believes to be original and

which he regards as important. It consists in introducing a bent iris forceps open between the lips of the wound, closing the blades, and gently withdrawing the instrument. A tag of capsule, he states, is frequently captured by the forceps, and is to be snipped off with scissors. The forceps is then similarly inserted at an adjacent part of the wound, and in this manner the wound is searched from end to end for capsule. A tag of capsule is found in about 25 per cent. of the cases. He instils a drop of eserine solution before the operation, and one drop of atropine sulphate solution afterwards. In the chapter on the lacrymal apparatus, speaking of obstruction of the canaliculi, Dr. Swanzy observes with great prudence that when it is necessary to have recourse to the operation of slitting up the canaliculus, the passage should not, if possible, be slit up in its entire length. At least 3 mm. of its median end ought to be left intact, otherwise the patient is liable to regurgitation of tears from the lacrymal sac for ever afterwards. In his account of the surgical treatment of convergent strabismus Dr. Swanzy though he mentions it, does not appear to be strongly in favour of the treatment recently advocated of advancement of the external rectus in place of or combined with tenotomy of the internal rectus. There is a very useful appendix, containing a full account of Holmgren's method of testing the sense of colour and the regulations as to defects of vision in the several Services. It cannot be too strongly insisted by family physicians that before a lad is sent to a "crammer's" or is made to work for one of the Services at school his vision should be tested by an expert. It saves much subsequent annoyance. There are very few typographical errors; but on page 539, speaking of the distance at which a gas jet should be placed behind a Maddox rod, "mm." is given, instead of *m*. The work is an excellent treatise for the student and general practitioner, the various diseases being well and clearly described, and the illustrations being numerous and accurate.

A Treatise on Appendicitis. By GEORGE R. FOWLER, M.D., Examiner in Surgery, Medical Examining Board of the Regents of the University of the State of New York, Surgeon to St. Mary's Hospital and to the Methodist Episcopal Hospital, &c. Philadelphia: J. B. Lippincott Company. 1894.

THIS volume of nearly 200 pages consists of a revised and corrected reprint of a series of articles which have been already published in the annals of surgery. Dr. Fowler has had unusual opportunities of studying the disease which he and many others call "appendicitis," and he has produced a treatise of considerable value. There are very few subjects on which current medical opinion has undergone a more complete and radical change than on the pathology and treatment of typhlitis, and there are very few diseases the pathology of which has been more carefully worked out. As the result of much labour it has been shown that changes in the vermiform appendix underlie all the cases that were formerly grouped in typhlitis, perityphlitis, and paratyphlitis, and the most advanced view of the therapeutics of these affections is that excision of this appendix is the only really satisfactory treatment for all cases except those of the most trivial grade. There are still some physicians and surgeons who hold that there is a disease which can only be rightly called "typhlitis," inasmuch as it originates in pathological changes in the cæcum—but certainly such cases are very rare and exceptional. A large number of practitioners are still unconvinced that surgical measures should always be taken in marked forms of this disease. That recovery may ensue upon even a severe attack of typhlitis without reverting to surgery is undoubted, but that is very far from establishing the position that the expectant treatment is the wiser course to pursue. The removal of the appendix in the early stage of the

affection is apparently the safest course to pursue if the surgeon operates with proper skill and precautions. One of the most interesting problems in pathology is the etiology of typhlitis. Dr. Fowler's view is that infection by pathogenic organisms is an all-important part of the process, and that, while the bacillus coli communis is constantly present and is the most important of the organisms found in exudations, other organisms are also present, and that the process is truly a multiple infection. This infection, however, he argues, is only secondary. It is led up to and rendered possible by some alteration in the appendix which renders it vulnerable. In Dr. Fowler's opinion this primary change is to be found in the bloodvessels or the nerves of the part. On the one hand, torsion and angulation of the appendix may impede the circulation, and endarteritis and thrombosis may occur; the pressure of an enterolith may also cause local anæmia. On the other hand, he thinks he has found evidence of an endo- or peri-neuritis, which, by causing trophic change in the part, may be the starting point of the disease. The changes he figures in both arteries and nerves may be the result of the local inflammatory affection, however, and not its cause. But in this chapter, as in all the others of the treatise, the subject is dealt with very ably and impartially, and discussed with great knowledge of the facts. The literature of the disease is very extensive, and much of it consists of hastily considered judgments or ill-digested observations; and it is, therefore, all the more refreshing to turn to a *brochure* marred by neither of these faults. Even those who cannot accept all Dr. Fowler's practical conclusions cannot fail to recognise the worth of the solid basis on which he founds them, or the admirably lucid and careful manner in which they are stated. Dr. Fowler has certainly made a valuable contribution to surgical literature.

Dr. William Smellie and his Contemporaries. By JOHN GLAISTER, M.D., F.F.P.S. Glasg. Glasgow: Jas. Maclehose and Sons. 1894.

DR. GLAISTER has performed his task, not as a mere compiler, but somewhat in the spirit of an original investigator; in fact, the preface implies that local patriotism was among the inducements which led him to the undertaking. Of course, much has already been written on the life and works of the famous accoucheur, but the present biography adds some useful details to our already existing knowledge of the subject and presents in a convenient form much information bearing on the history of midwifery in the seventeenth and eighteenth centuries.

William Smellie was born in the town of Lanark in 1697. He probably received the rudiments of a medical education as an apprentice to a surgeon in Glasgow, and, though not in possession of a legal qualification, established himself as a general practitioner in his native place about 1720. In 1724 he married, and in 1733 he became a Member of the Faculty of Physicians and Surgeons of Glasgow. Towards the end of 1738 or beginning of 1739 he left Lanark for London, soon proceeding to Paris, where he remained at least three months, attending the midwifery lectures delivered by Grégoire. Probably in the same year, 1739, he returned to London and commenced practice as an accoucheur and apothecary in a humble way in the vicinity of Pall Mall. The principal teachers of midwifery in London at this time were Dr. John Maubray and Sir Richard Manningham. The former had received pupils at his house in Bond-street as far back as 1724, and had published two treatises, in one of which obstetrics were combined with astrology and mysticism. Sir Richard Manningham was just beginning to give instruction in St. James's Infirmary, Westminster, where in 1739 a ward was set apart for lying-in women, being apparently the first separate maternity institution in this country. Smellie

mentions in his third volume that he himself was a teacher of midwifery in 1741, and Dr. Glaister's researches have elicited that on Feb. 18th, 1745, the University of Glasgow conferred on him the degree of M.D. *in absentia*. By 1748 he had attained such celebrity and trained so many pupils as to draw on himself the active hostility of the midwives and of several practitioners who disapproved of male obstetricians. As his success increased he removed from Pall Mall to Gerrard-street, and afterwards to Wardour-street, Soho, which reads oddly nowadays. In 1751 (see p. 165) he published his first volume, an octavo, entitled "A Treatise on the Theory and Practice of Midwifery," and the London *Monthly Review* for December of that year gave it a very favourable reception. In 1754 he brought out a second volume describing 274 obstetric cases, the majority of which had occurred in his own practice. This work was revised for publication by Tobias Smollett, the novelist, who mentions it in a letter written from Chelsea to Dr. Moore in Glasgow. Dr. Glaister reproduces this letter by an excellent photoprint, which would have been still better if not so much reduced in size. Accompanying the second volume there appeared in folio form his "Anatomical Tables," consisting of thirty-nine plates and containing the first published drawing of his straight and curved forceps. He used French forceps as far back as 1737; between 1744 and 1745 he invented the familiar method of locking the blades, and before 1748 he gave the instrument that form which is still known by his name. He also invented the perforating scissors, which was the prototype of the modern perforator. In his directions for performing craniotomy he "for the first time detailed the steps of an operation which in practically every feature has been followed by every enlightened accoucheur and by every writer on obstetrics since his day." In 1759 he retired from practice and returned to Lanark, his native place, where he worked at the preparation of his third volume until his death in 1763. This third volume, edited probably by Tobias Smollett, appeared in 1764, and was entitled "A Collection of Preternatural Cases and Observations in Midwifery," by W. Smellie.

The biography would have been improved by greater conciseness of style and by the omission of a few inelegancies such as "scatologic medicine" (on p. 171), a Greek synonym for "fecal" being quite needless. Many of the Latin words and quotations contain obvious typographical errors, as on pp. 35 and 229, and elsewhere. The author has, however, collected and examined his materials with unusual care and has produced a book of no small merit.

Syphilis. By ALFRED COOPER, F.R.C.S. Eng. Edited by EDWARD COTTERELL, F.R.C.S. Eng. London: J. & A. Churchill. 1895.

TEN years have elapsed since the appearance in 1885 of the first edition of this work, and in the present issue, which has been edited by Mr. Edward Cotterell, all the chapters have been revised, several have been entirely rewritten, and a chapter on the Relation between Syphilis and Insanity has been added. After a short account of the history and geographical distribution of syphilis a description is given of the ordinary course of the disease. Then follows a discussion of the "unity" and "duality" theories, which now do not possess either the interest or importance they once had. The general and local manifestations of syphilis are well described, and a chapter is devoted to the inherited form of the disease. The question of the prevention of syphilis is discussed, and a chapter on the various methods of treatment concludes the volume. The chief new feature of this edition is to be found in the illustrations, which are contained in twenty plates, and of these eleven are coloured. All the illustrations are of a high order of excellence, but chief praise must be given to the coloured plates, which are reproductions of original

paintings taken for this work; they represent very graphically some of the more characteristic syphilitic eruptions. Plates X., XI., and XIII. are especially worthy of commendation. The microscopic appearances are well represented in the drawings, four of which are reproduced from Dr. Radcliffe Crocker's work on the Skin. We may say, in conclusion, that the work in its present form contains a very satisfactory exposition of the present state of our knowledge with regard to syphilis.

JOURNALS.

Teratologia: a Quarterly Journal of Antenatal Pathology. Edited by J. W. BALLANTYNE, M.D., F.R.C.P. Edin., F.R.S.E. Vol. II., No. 1. London: Williams and Norgate. January, 1895. It speaks well for the width of view now embraced by pathology, and the activity exhibited in its pursuit, that a scientific journal should be founded with the sole object of recording facts in foetal pathology and congenital anomalies. The contents of the present number, which begins a new volume, prove that the topics are of wide and varied range, that there is much to be learnt in a field that has been comparatively neglected, and that the studies in this department are full of promise for the elucidation of many problems and the rectification of many theories. Dr. Ballantyne is to be congratulated upon his efforts to disseminate this new learning in the cause of pure science. The first paper is by Dr. John Thomson on a Form of Congenital Thoracic Deformity, based upon a collection of eighty-six cases on record, together with three others that he has himself observed. Briefly, the deformity consists in unilateral defective development of the chest wall, hair, subcutaneous fat, breast, pectoral, and other muscles, costal cartilages, and anterior ends of ribs, associated with deformity of hand and forearm. The defect is not analogous to the condition of mesial fissure, but is probably due to intra-uterine pressure affecting the side of the thorax and the upper limb. The paper is fully illustrated. Dr. William Osler records an example of Cerebral Hemorrhage in a Six Months Fœtus, removed after the death of the mother. The editor describes a case of Pre-auricular or Branchial Appendage, and in another article enters into the history and associated pathology of the whole subject. Several reviews and a copious collection of abstracts from current literature make up a very interesting number of a periodical which may be commended to the notice of pathologists.

Archiv für Pathologische Anatomie und Physiologie und für Klinische Medicin. Herausgegeben von RUDOLF VIRCHOW. Band cxxxix., Heft 1. (*Archives of Pathological Anatomy and Physiology and of Clinical Medicine*. Edited by RUDOLF VIRCHOW. Vol. cxxxix., No. 1.) Berlin: G. Reimer. 1895.—In spite of the increasing number of channels for the publication of original contributions to medical science the popularity of *Virchow's Archiv* is unabated. Of this famous journal four volumes have appeared annually since 1878 in place of three a year as formerly, but the editor is, notwithstanding, compelled to address some words of warning to his contributors to condense their material and limit the number of their illustrations. The number of papers now in his hands is so large that it is proposed to publish a supplementary part to the just completed volume (the 138th), and, if necessary, to issue another similar supplement subsequently. This is not the first time that Professor Virchow has been impelled to ask his contributors to be concise and forbearing. In 1878, and again in 1881, he made a similar appeal. Amongst the papers of marked interest in the number just issued are the following: On Parasitic Ictero-Hæmaturia in Sheep: a Contribution to the Study of Amœbo-sporidia, by Professor Bonomo of Padua; on the Etiology of Parenchymatous Nephritis (Puerperal Eclampsia, Ptomainæmia), by Dr. A. Favre of Neuchâtel; F 3

on Normal and Inflamed Cardiac Valves, by Dr. Veraguth of and Zurich; and on Oedema of the Larynx and Submucous Laryngitis, by Dr. Kuttner of Berlin.

New Inventions.

A MODIFICATION OF THE BIVALVED SPECULUM.

IN the leading article on "Advances in the Treatment of Uterine Fibroid Tumours," which appeared in THE LANCET of Jan. 19th, 1895, the words occur: "Many prominent operators in America and on the Continent practise total extirpation of the uterus in cases of uterine fibroids." May I be allowed to point out that this practice has also been adopted for some time in this country, notably by Dr. Smyly (Dublin), who, in the paper he read before the British Medical Association meeting at Bristol last year, recorded fifteen cases, with two deaths, Mr. Greig Smith and myself. I have performed total extirpation for uterine myomata on three occasions, each case making a good and speedy recovery. As the operation I adopt differs somewhat from that as performed by Martin in Berlin or Dr. Smyly it will not be out of place to briefly describe it. For the purpose of the operation in my first cases I used an ordinary Fergusson's speculum, which answered the purpose fairly well, but I have had made for me by Messrs. Weiss a modification of a bivalved speculum, which I now use. (See Fig.)

The abdomen being opened in the middle line and the tumour delivered through the wound, the broad ligaments are ligatured and divided on each side. Small anterior and posterior flaps of peritoneum are raised from the uterus, the bladder being pushed away in front and the rectum behind. The speculum, which is nine inches long, is introduced into the vagina and held in position by an assistant, and is now pushed well home, and, the assistant pressing on the outer ends, the blades are forced open and the roof of the vagina put upon the stretch. It is then an easy matter to cut into the vagina from above on to the ends of the blades of the speculum in front and behind. This being done, the uterine arteries are readily secured by ligatures and the tissues between them and the cervix uteri divided. The myomatous uterus is then lifted out of the abdomen. Any bleeding points being secured by catgut ligatures, the peritoneal flaps are closed by passing long sutures (about six in number) in the following manner. The needle, threaded with a No. 4 silk suture, is passed from the raw surface through one of the flaps, and then over and through the other flap from the peritoneal surface; these are tied in long loops and conducted through the speculum down the vagina and pulled taut, the effect being to evert the flaps into the vagina, thus securing the peritoneal surfaces into accurate apposition. The loops can be withdrawn the next day. The vagina finally is washed out with carbolic lotion and packed with iodoform gauze. The abdominal wound is closed in the usual manner.

FRED. BOWREMAN JESSETT, F.R.C.S.

Buckingham Palace-mansions, S.W.

THE ENEMA RACK.

INDIARUBBER enema syringes which are habitually kept in their boxes when not in use suffer very much from the long-continued bending of the tubes. The material has a natural tendency to become hard in course of time, and the result is one or more curvatures in the tube. To meet this difficulty Messrs. Reynolds and Branson, 13, Briggate, Leeds, have introduced an enema rack, consisting of a stout tinned wire,

rather over two feet long, jointed in the middle for portability and having fixed loops at one end and at the other a support for a small bottle. The valved end of the syringe passes through one of these loops, and by the other loop the whole can be suspended in a vertical position with the nozzle of the syringe in the bottle so as to avoid any drip or splashing. The device is perfectly simple and of obvious utility.

THE WITTMANN FILTER.

THIS filter may justly claim to be free from the complicated structure of most filters, which makes it difficult to ascertain when a filter is foul with impurities or when it is necessary to replace the filtering medium. In the Wittmann filter the medium consists of a well-prepared animal charcoal fashioned into the shape of a bowl about four inches deep, and it is this feature which constitutes the real novelty of the device. The charcoal bowl simply rests upon a narrow gallery or ledge provided on the inside of a glass reservoir or other suitable receptacle. Apart from the purifying powers which well-burnt animal charcoal is known to possess, especially in regard to deodorisation and decolourisation, this arrangement, we find, is effectual in bringing the filtered water into intimate contact with the air, and by its constant fall in drops under conditions of free exposure to the air a maximum degree of aeration is secured. While also the filter will remove from the water impurities which will accumulate in course of time according to the quality of water with which it has to deal, these may easily be removed by cleansing and immersing the bowl in boiling water as occasion may require. Everything being exposed to view, the time when this should be done will be manifest. On this account the use of this filter is calculated, we think, to ensure the consumption of clean and bright water. We notice that Drs. Sims Woodhead and Wood in their bacteriological report upon this filter, remark that, "although its filtering capacity is above the average, it offers no effective impediment to the direct passage of micro-organisms." The filter is made by Messrs. Wittmann and Roth, 47, Great Marlborough-street, W.

THE LIVERPOOL WATCH COMMITTEE AND THE VACCINATION OF THE POLICE.—The Watch Committee of Liverpool have had their attention drawn by Mr. F. W. Lowndes, one of the surgeons to the police, to the fact that a proportion of the recruits applying for admission to the force have no vaccination scars on their arms at all, while very few have undergone revaccination. They have resolved that in future every man before admission to the force be required to prove to the satisfaction of the police-surgeon that he has been efficiently vaccinated or revaccinated. It was also resolved that such members of the force as may desire it be vaccinated or revaccinated by the police-surgeon free of cost; that they be upon the "hurt list" if necessary; that the police-surgeon be paid for each case one shilling; and that the cost of lymph be paid by the corporation. The principle of practical compulsory vaccination has been admitted by the State for many years past, the men of the army, navy, militia, and postal and other services being obliged to undergo revaccination before being appointed. The same remark applies to members of the Metropolitan Police Force, the Royal Irish Constabulary, and other police forces throughout the kingdom. It is greatly to be hoped that the same rule will be enforced wherever required, policemen being very liable to be exposed to the contagion of small-pox.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 9, 1895.

On Friday, Feb. 1st, a large and influential deputation, including almost all the leading ophthalmic surgeons in Great Britain, waited upon Mr. BRYCE, the President of the Board of Trade, to impress upon him the extreme importance of applying scientific tests to the eyes of men and officers about to join the mercantile marine or the railway services. The chief points which were emphasised by Mr. MACNAMARA, who introduced the deputation, and by the speakers who followed him, were that every man should be tested in regard to his vision both for form and colour; that this examination should be conducted by a responsible person, and, if possible, by an expert; that the conditions in regard to light and distance should be as uniform as possible; and, lastly, that the examination should be repeated at stated intervals in order that any deterioration resulting from disease or from the advance of age might be detected. It was urged, and rightly urged, that such tests were already in use in the army, navy, and Indian services, and more especially on the Indian railways, and that no difficulty was experienced in obtaining a sufficient number of competent men without visual defects for those departments. Mr. BRYCE, in reply, whilst acknowledging in a very courteous manner the great weight and influence of the deputation, contended that the Board of Trade had shown that they were already fully alive to the importance of the subject. The Board of Trade, he remarked, possessed only limited statutory powers; but quite recently, in the autumn of last year, a modified and improved method of examination had been instituted, by which the eyes of all candidates for the posts of master mariners and of mates were tested; beyond that the Board was not empowered to go. It had no statutory powers in regard to railway officials.

This reply, however, does not quite touch the root of the question. Examinations may be instituted, but the real question is, Are they carried out in a thoroughly satisfactory manner? It was, moreover, shown by more than one of the deputation that no effort is even now made to determine the refraction of the eyes of the candidates, and that consequently cases of hypermetropia and of astigmatism may present themselves with sufficient acuteness of vision to enable them to pass muster and yet be inadequate, after the lapse of a variable period, for the due discharge of their duties. When we consider that the modern liner not infrequently cuts the water at the rate of a mile in three minutes; that she carries from 300 to 1200 passengers, besides a cargo of the value of many thousands of pounds; that there are scores of such ships afloat; that, as the late accident has demonstrated, she is liable to be sunk in less than half an hour by a blow affecting a vital part delivered by a comparatively small vessel; and, lastly, that the recognition of any danger ahead in time to enable it to be averted is dependent upon the keenness of sight and correctness of colour vision of two or three

men on the look-out—when we consider all these points surely we are entitled to demand that every possible precaution to prevent disaster that knowledge and science can suggest should be exercised, and that no pains should be spared to debar the entrance into responsible positions of men whose defect is often not from any fault of their own, but a congenital imperfection. It may be perfectly true, as Mr. BRYCE remarked, that very few, if any, accidents, the causes of which have hitherto been the subject of investigation, can be shown to have resulted from the visual defects of the officers or men on board our mercantile marine; but it will be acknowledged by all that where so much life and property are at stake it would be madness to overlook an extremely probable though recently discovered source of danger. The old adage of "Forewarned, forearmed" may still be borne in mind, especially as the defects in question afford a reasonable explanation of accidents for the cause of which no plausible suggestion has been made. That which is true of the mercantile marine holds, in the same sense, for the railway service, and two cases reported in our issue of this week by Mr. W. M. BEAUMONT show well that the danger to the public who travel by rail from the visual errors of railway servants is not imaginary. The possession of normal acuteness of vision and of normal perception of colour is imperative among railway officials no less than among sailors for the safety of life and for the protection of property.

The contention advanced by Mr. BRYCE that the railway companies are sufficiently alive to their own interests to prevent men with defective vision entering their service is well founded, and it appears that several of the larger companies have taken the precaution to appoint a competent surgeon to examine all candidates for admission to the service. Yet even in these cases it seems to be doubtful whether the refraction of each eye is accurately determined. It would do no harm if, as Mr. LEET suggests in his letter to us, some responsible adviser, some professional head analogous to the Director-General of the Medical Departments of the Army and the Royal Navy, were appointed, whose business it should be to see that the recommendations and orders of the Board of Trade on this point are carried out, and to whom all complaints might be referred. This appointment would not enable the railway companies to shirk their responsibility on the ground that the State certificate superseded their own duties, as Mr. BRYCE thought would occur if the tests were applied by a Government official. It would simply ensure that the provisions for the safety of the travelling public were duly enforced. The frequency with which colour-blindness occurs in the population generally is known to be about 3 or 4 per cent.; but it may be of interest to state that the number of candidates for masters' and mates' certificates of competency in the British mercantile marine who failed in the colour test during the fifteen months ending with August last year—that is, before the more recent and better mode of testing the eyes for this defect had come into play—was no less than eighty-one, every one of whom in old days would have been permitted to enter the service without question, but to the manifest danger of Her Majesty's subjects. The suggestions of the deputation that the eyes of all candidates for the mercantile

marine service should be tested for keenness of vision and for colour sense, and that the condition of refraction should be accurately determined by a competent examiner at regular intervals, seem to be not only prudent but absolutely necessary, whilst they present no difficulty that render their adoption impracticable.

THERE is no longer the least doubt that Lord RAYLEIGH, Sec.R.S., and Professor RAMSAY, F.R.S., have made a most important discovery, and the most remarkable thing connected with it is that the new element (or it may be elements) has been separated, not from any rare earths or other comparatively unknown source, but from our own familiar friend the air we breathe. "Argon" has thus escaped the notice of investigators for nearly a century, and its probable existence was only lately surmised by a physicist when he observed that the density of nitrogen expelled from chemical compounds was about $\frac{1}{2}$ per cent. lighter than atmospheric nitrogen; its actual separation and identification seem, however, to have been reserved until both chemist and physicist attacked the problem. The former was Lord RAYLEIGH and the latter Professor WILLIAM RAMSAY, and the result of their joint labour is a happy instance of the success which attends the coöperation of those who, though engaged in different but adjoining fields of scientific research, yet labour in concert to unfold the secrets of nature. It is not possible to enter into the masterly and extremely interesting argumentative details of the paper contributed by Lord RAYLEIGH and Professor RAMSAY, the reading of which by the latter riveted the silent but expectant attention of the Fellows of the Royal Society and their friends in the theatre of the London University on Thursday afternoon last week. Suffice it to say that the history of the progressive stages of the investigation was not the least fascinating portion of the paper, as were also the clear and lucid arguments and experimental evidence adduced, which left the distinguished audience in little doubt as to whether the element or constituent separated was really new or old. We may, therefore, pass at once, in accordance with the plan of the chemical text-books, to a brief account of the history, preparation, and properties of the new element. By way of preface, however, it is impossible to forget the classic work in the last century of CAVENDISH on the composition of the air, which must appeal once more to the wonder and admiration of present-day chemists and physicists, his power of discernment being, in the light of this recent discovery, more clearly evident than ever before, since in his remarkable paper published in the Philosophical Transactions in 1788 he expresses doubt as to whether the nitrogen of the air (phlogisticated air) was in kind elementary, and he even adduced distinct experimental evidence—based on the oxidation of nitrogen by means of the electric spark and subsequent absorption of nitric fumes—of another constituent in the atmosphere. Thus he wrote, "If there is any part of phlogisticated air of our atmosphere which differs from the rest and cannot be reduced to nitrous acid we may safely conclude that it is not more than $\frac{1}{15}$ th part of the whole." This residue was, no doubt, Lord RAYLEIGH's and Professor RAMSAY's argon, which occurs probably to the extent of between $\frac{1}{15}$ th and $\frac{1}{10}$ th part of the whole atmosphere.

It was by repeating the Cavendish experiment, with the facility of appliances which the improvements of a hundred years have afforded, and by adding successive quantities of air out of which the nitrogen was eliminated in the manner indicated, that Lord RAYLEIGH and Professor RAMSAY showed that the residue could not be nitrogen, but another body, which they have called "argon." Under similar treatment chemically obtained nitrogen yielded no such residue, except such as could be accounted for by accident or other cause. Argon is best obtained, however, by first freeing the air, from which carbonic acid and water have been removed, from oxygen by means of red-hot copper and then absorbing the nitrogen by means of metallic magnesium, which, when heated to redness, combines with the nitrogen, forming an orange-coloured mass of magnesium nitride. The residual gas after this series of operations—the passage of the gases being repeated again and again—is argon. In this process, again, chemically derived nitrogen yields no such residue. The density of pure argon is 20; hence its molecular weight in accordance with Avogadro's law must be 40. There are reasons for believing that, like mercury, its molecule contains but one atom; its atomic weight, 40, is therefore identical with its molecular weight. Argon is soluble to the extent of 4 volumes per 100 volumes of water, so that it is about two and a half times as soluble as nitrogen, and possesses approximately the same degree of solubility as oxygen, and is accordingly found to occur in increased proportion to nitrogen in rain water. According to Dr. OLSZEWSKI, a well-known authority on the constants of liquefied gases at low temperatures, argon easily condenses to a colourless liquid at a temperature of -128.6°C . and under a pressure of thirty-eight atmospheres. At a lower temperature argon freezes to a crystalline mass like ice; at a still lower temperature it becomes white and opaque. Its freezing point is -189.6° , its boiling point -187° , and its density as liquid is 1.5. As far as spectroscopic work can decide Professor CROOKES concludes that Lord RAYLEIGH and Professor RAMSAY have added one, if not two, members to the family of elementary bodies. It appears that argon yields two distinct spectra, and this would indicate it to be in reality a mixture of two gases, which have as yet not been separated. On the other hand, Dr. OLSZEWSKI has shown that argon has a definite melting point, a definite boiling point, and a definite critical temperature; and these, as is well known, afford excellent criteria of a pure substance, while there is no certainty that the exhibition of several spectra is necessarily characteristic of a mixture. Still further light, however, is needed upon this all-important point, and the discoverers hope to decide the question in the experimental work which they promise shortly to undertake. If argon be a single element, then there is reason to doubt whether the periodic classification of the elements is complete—whether, in fact, elements may not exist which cannot be fitted among those of which it is composed. On the other hand, if argon be a mixture of two elements they might find place in the eighth group in Mendeleef's classification, one after chlorine and one after bromine. If it be supposed that argon belongs to the eighth group, then its properties would fit fairly well with the requirements of the periodic law. For the series which contains silicon, phosphorus, sulphur, and chlorine

might be expected to end with an element of mon-atomic molecules of no valency—i.e., incapable of forming a compound, or, if forming one, being an octad; and it would form a possible transition to potassium with its monovalence on the other hand. "Such conceptions are, however, of a speculative nature, yet they may perhaps be excused if they in any way lead to experiments which tend to throw more light on the anomalies of this curious element." Lastly, the extreme indifference or inertness of argon to combine with other elements, in spite of its solubility in water, is remarkable. This property has suggested its name, which is derived from *ἀργον*, the same word being used in the Greek Testament in the familiar passage about "every idle word." All attempts to combine argon with the bodies which commonly exhibit a vigorous affinity for certain elements have proved utterly abortive. Fluorine, which lays siege to almost every known body, has, however, not been tried. In this connexion it should be borne in mind that it is nitrogen's very inertness which makes it so powerful an agent in modern high explosives; it strongly resents partnership or a tied existence, as does apparently argon, and longs to exchange the solid condition for the gaseous. We are face to face, then, with a mass of remarkable evidence, brought forward with singular skill and clearness by the discoverers, in favour of the existence of a new constituent of the atmosphere. It has stood unflinchingly the minute and exacting investigations of Dr. OLSZEWSKI and Professor CROOKES, and the discoverers have received the congratulations of the presidents of the learned societies, so that, regarding the important contribution in the light of a proposition, we may write conclusively at its end Q.E.D.

That being so, what, we may ask, is the significance of this newly discovered constituent of the atmosphere? Does, for instance, its presence affect the phenomenon of respiration or of the assimilation of food material by plants? Would not its solubility in water, which is greater than nitrogen and equal to oxygen, lead to its transmission through the moist membrane of the lung, and, if so, what part does it play in the physiological processes in man upon which his very existence depends? Does its alternating presence in the air possibly account for the bracing influence of sea and mountain air, and are the benefits of balneo-therapeutics, *inter alia*, to be ascribed to argon? Again, is it nitrogen or, after all, argon that is disengaged from certain warm mineral waters, as those of Buxton? All these and other questions of probable importance will at once occur to our readers when they learn the existence and the properties of the new atmospheric constituent. Who can tell, therefore, that the discovery of argon may not open a new vista even to the student and practitioner of medicine? It is certain that now the existence and position of argon have been indicated, as with a new planet or comet, a host of observers will turn their instruments upon it and many deductions on these and other points are sure to be orthcoming.

It is pardonable perhaps in the vacation season for our lay contemporaries to devote their columns to the discussion of a very old question—the propriety of medical men dispensing their own medicines. The opening of Parliament

will no doubt see the termination of such a discussion long before the question is settled to the satisfaction of either side. Some good things have been said on both sides, and some very foolish things. The subject is one which admits of no dogmatic treatment, and one on which every medical man must be allowed to do that which he deems best in the circumstances of his particular practice. One of the foolish arguments is adduced in favour of a medical man writing prescriptions. It is to this effect—that he thereby gives his patient an opportunity of judging of the propriety of the treatment, for the patient can then see what the medicines prescribed are, and by consulting a book on *materia medica* can tell whether the medical man is acting rightly; as if the patient were a detective to watch his medical man suspiciously, and capable of judging his treatment by reference to any old book on medicine that might be at his finger ends. Not very much more serious is the argument from the suggestion that medical men often injure their patients by mistakes of dispensing, but that nothing comes of it because of their power of filling up certificates of death. The teaching of pharmacy in medical education, though more and more insisted on, is not so perfect as it should be; but it is to medical men that we owe all precautions of therapeutics and the wisdom of giving the smallest doses of drugs that are compatible with their usefulness. They cannot be free from the responsibility of dispensing their most powerful drugs, for they have to do so in all night practice and in lonely and remote places. It is essential that they have this faculty in the interest of their patients and for their speedy relief. Readiness is a great part of the value of any medical man—"His ready help was always nigh,"—the ability to act and to relieve without waiting for the assistance of druggists or nurses or any subordinates. They would deprive the general practitioner of a great power of usefulness who would dissociate him from the manipulation and preparation of drugs. They might as well, and better, dissociate him from the use of his splints and pocket-case. One writer in our contemporary, the *Birmingham Daily Mail*, says truly that there are in that city medical men who give their professional services and supply medicine at the rate of one penny per week per head! Would that Birmingham—"the best governed city in Europe"—were alone in that respect. Medical men are not entirely to blame for this mean arrangement. It is dictated by the "sweating" views of the committees of medical aid associations, medical clubs, &c. But medical men are not without blame and must feel that they place the profession in an undignified and false position. We are not concerned to defend those who thus bring medical service into contempt. They have been condemned by the general judgment of the profession and the implied judgment of the General Medical Council.

But while we demand for the medical practitioner the right to dispense—that is, full control over the immediate and direct use of drugs—we are quite favourable to the delegation of the drudgery of dispensing to druggists wherever this is practicable. In country places and in poor districts or practices it is not practicable; but in other places and circumstances it is practicable and should be practised. The neat and careful preparation of medicines is of such importance that it may properly be delegated in

favourable circumstances to one specially devoted to it. It is not the fault of medical men that such an arrangement as is said to obtain at Margate is not in much more extensive use, where medical men and druggists are under mutual obligation—within reasonable limits of course—the former not to dispense and the latter not to prescribe. If druggists would show less disposition to prescribe and to make secondary uses of medical prescriptions, and if they would contrive better to adapt their charges to the means of patients as medical men have to do, they would do much to hasten this division of labour. It is no part of this argument to disparage the legitimate business of druggists, which is a dignified and worthy one; but we deny entirely their right to prescribe. The General Medical Council at every meeting removes from the Register medical men for allowing unqualified practitioners to act as if they were qualified. This is what many druggists do, even in grave cases, often with grave results; and it hinders that coöperation and confidence of medical men which we all desiderate.

Annotations.

"Ne quid nimis."

SEWAGE ORGANISMS AND DISEASE.

IN previous reports¹ presented to the London County Council Mr. J. Parry Laws, F.I.C., made the important observation that the micro-organisms contained in sewer air were not only less in number than the micro-organisms in fresh air in the vicinity at the same time, but that they were also apparently related to and derived from those of fresh air rather than sewage, while there was no evidence forthcoming that sewage was able to give off micro-organisms to the air in contact with it. Acting on the instructions of the Main Drainage Committee of the Council this investigation has been extended by Mr. Laws, with the assistance of Dr. Andrewes, to a study of the organisms existent in sewage. From a copy of the valuable report which has recently been issued, and which contains a careful series of well-chosen and laborious experiments, we gather the following materials. The most striking difference in the bacteriology of sewage and sewer air appears to be the absence of moulds from the latter, while in the former moulds were found to be a predominant feature. The bacillus coli communis was found, with one exception, in each sample of sewage examined, but neither it nor its allies were ever found in sewer air. The bacteria of sewage rapidly liquefy nutrient gelatine, while organisms possessing this property were practically absent in sewer air. This evidence would seem to be conclusive that there is no relationship between the organisms of sewer air and sewage, and the writers are thereby led to think that some of the ill-effects which have been erroneously (?) ascribed to sewer air may be due to subsoil air derived from soil polluted by constant infiltration of excremental matter, but suggest that it is not until the outer margin of the permeated soil has become dry that the air is infected with organisms. In a search for the typhoid bacillus in sewers, where it might be expected to be present in large proportion, such as in the drains of the Eastern Hospital at Homerton, they were successful in demonstrating the actual presence of the bacillus typhosus; but in a sample taken about a quarter of a mile away no single colony developing on culture could be referred to the bacillus of typhoid fever. In the light of this and other

results it is concluded that sewage, even in the absence of the normal micro-organisms which it contains, is clearly an unfavourable medium for the growth of the typhoid germ, whereas the colon bacillus can grow and multiply freely in it. It might be anticipated, it is pointed out, that in competition with other organisms, able to grow well in sewage, the typhoid bacillus would die out even more speedily. These experiments are only preliminary and are necessarily incomplete, but they give a distinct indication of the probable fate of typhoid bacilli which gain access in a living condition to sewage, while it seems "clear that sewage does not form a medium in which much, if any, growth is possible for them under natural conditions, and their death is probably only a matter of a few days, or at most one or two weeks." Obviously, this resistance to growth may be overcome by attenuation, as when sewage has access to the drinking supply or to milk. It would appear, then, that so far as bacteriological analysis goes there is no ground for believing that sewer air plays any part in the conveyance of typhoid fever; but are the conditions under which the bacteriological examinations of sewage and of sewer air are made such as to give us absolute assurance on these and other points? In spite of its apparent bacteriological innocuousness no one entertains the least doubt that sewer air is a constant source of disease, and if this is not to be referred to micro-organisms to what may it be ascribed? There is undoubtedly a poisonous agency at work when sewer air is inhaled, which, though it may not directly act, yet so prepares the soil that the system is unable to resist the invading organism when it comes. In some well-known experiments recorded in THE LANCET² it was shown that when rats, amongst other animals, were inoculated with a weak growth of typhoid culture, after previously being exposed to sewer emanations, they nearly all succumbed. On the other hand, rats treated to the same dose of typhoid culture, but exposed to fresh air after inoculation, showed little sign of illness and eventually recovered. What, then, is this poisonous constituent of sewer air which leaves the system defenceless against the attacks of the microbes which it may encounter? An investigation on this point would form, we suggest, an excellent and fitting sequel to the above valuable contribution.

SNOW SALT, AND SLUSH.

EVERYONE will agree that the severe and bitter cold we are experiencing just now hardly requires accentuating. Eight degrees of frost all day in London, with probably twice that number registered in the suburbs, require no ordinary amount of endurance on the part of pedestrians, but to reduce this to zero by artificial means on the pavements of our streets is intolerable and unnecessary. Yet the sprinkling of salt in the streets appears to be the only means which has occurred to the street authorities for removing the fallen snow. It is a matter of common knowledge that such a mixture produces instant liquefaction and consequent great absorption of heat, and the temperature of the resulting mixture, *pro tempore*, sinks to zero. But this is not all; the mixture, being saline, remains wet at a temperature considerably below freezing point, so that the pavements are made much more uncomfortable and cold than they would be if nothing at all was done. There is little doubt also that the salt solution, finding its way into the soles of boots, renders them permanently damp and therefore permanently cold. The roads (for we must bear in mind our four-footed friends) and the pavements should be swept immediately after a fall of snow, or, if salting must be done, the saline slush could be "squeezed off" the moment it is formed so that we may have at least a dry footway. The street sanitary authorities should surely use their powers and, if unable to do the work

¹ THE LANCET, March 24th, 1894.

² THE LANCET, Sept. 29th, 1894.

themselves, encourage the occupiers of each shop to keep the adjoining pavement properly and promptly clear of snow for the comfort of the passers-by, amongst whom must be reckoned their customers. It is well known that the prevalence of cold weather is a factor which largely contributes to increased mortality, chiefly referable to diseases of the respiratory organs, and some little care should, therefore, surely be taken to exclude anything that is calculated to aggravate any liability of this kind. Prolonged and excessive coldness with dampness of the feet is a likely enough source of illness, and what is calculated to produce cold and wet feet more effectually than a wet freezing mixture, which is exactly what our feet are exposed to when snow is sprinkled with salt?

THE ABUSE OF MEDICAL CHARITIES.

WE see with much satisfaction that the *Westminster Gazette* is publishing a series of articles on the above subject by "Scrutator." It is of great importance that the lay press should take up this subject and impress it on the public mind. In his first article "Scrutator" says that in the majority of cases hospital managers in no way concern themselves with the abuse practised on their institutions by those for whom they were never intended. The sole concern of the managers is to give an imposing account of the numbers relieved, and especially to show that they are increasing at an ever-increasing ratio. If their appeal to the public for more funds cannot be based on the fact of an enlargement of premises the next favourite basis is an increase in numbers. This, of course, is chiefly in the out-patient department, while the accommodation for in-patients is often a diminishing quantity and consists in displacing poor patients for those who can pay. Such evils are familiar to the medical profession, and will increase year by year unless public feeling is aroused to condemn them. If we might be allowed a word of criticism on "Scrutator's" first article on this subject we would say it deals too much in general statements. The strength of the case is in details of individual hospitals, and in close investigation of the circumstances of individual cases.

FIRST AID ON SHIPBOARD.

THAT measure of acquaintance with the rudiments of medical and surgical knowledge which is comprised under the term "First Aid" is probably more essential to seafaring men than to any other class of the community. The nature of their adventurous calling exposes them continually to bodily risks of all kinds, and limits each ship's company to its own resources in the event of any illness or injury, however grave. The Passengers Act requires that British foreign-going vessels on which there are fifty passengers shall carry a medical man, and the Merchant Shipping Act has a like requirement in the case of all foreign-going vessels having 100 or more persons on board. The large number of vessels not fulfilling these conditions, and consequently not provided with medical officers, affords frequent opportunities for amateur surgical practice at sea, some interesting particulars of which were given by Mr. A. M. Cato, M.R.C.S., L.R.C.P., in a paper read before a meeting of the Shipmasters' Society, London, held on Jan. 21st at the Fishmongers' Hall. He states that the sailing ships and steamers which do not carry surgeons number about 5600, and that their crews amount to the large total of about 140,000 persons. The numerous cases of disease and injury occurring among this great body of men, scattered everywhere over the face of the ocean, are necessarily treated by the officers of the vessel, who have at their disposal the stock of drugs authorised by the Board of Trade and contained in the medicine chest. Some guidance in the use of these medicines is provided in a small "Book of Directions,"

also contained in the chest. In nautical life surgical emergencies are perhaps more numerous, and certainly more conspicuous, than equally urgent illnesses requiring medical treatment. As the ship's officers will in most instances have the management of these cases to their termination, something more than the ordinary first aid will often be required. Mr. Cato judiciously proposes that when the classes are composed of seafaring men the five lectures constituting the first aid course of the St. John Ambulance Association might be somewhat extended. Another recommendation of his—viz., that ship's surgeons might be authorised to give first aid instruction while at sea—is well deserving of favourable consideration. The officers and petty officers who have learned something in this way will naturally in the course of their service find themselves on board vessels on which there is no surgeon, and opportunities for putting their knowledge in practice will sometimes occur. It is satisfactory to find that the Board of Trade acknowledge the utility of instruction in first aid by endorsing on an officer's certificate of rating the fact that the owner also possesses the certificate of an ambulance association.

A SPECIFIC AND ITS SUPPORTER.

A CORRESPONDENT signing himself "M.D." has written to the *Morning Post* advocating the employment of a certain substance in the treatment of diphtheria. He says, "I know neither its origin nor composition," and yet he does not hesitate to guarantee the nostrum as "absolutely safe," or to try to lead his readers to believe that it acts as an infallible specific. The apology advanced by "M.D." for addressing his communication to a lay paper is in itself condemnatory. "I take the unusual course of publishing it in your journal because it will thus be brought directly before the public without loss of time, whereas in a medical paper it would probably receive no notice unless I were to publish a detailed report of some hundred cases." An anonymous endeavour to puff a quack remedy would not be worthy of notice if it were not for the fact that the communication containing it appears in the columns of a highly influential and well-conducted paper. This fact we take to be a sufficient guarantee that the writer is in reality what he professes to be—a medical man; and we feel bound to draw his attention to the grave irregularity of which he has been guilty. It is possible that a letter from the sole agent for the company supplying the drug, which appeared in the *Morning Post* four days after his original communication, has already opened his eyes.

A NICE DERANGEMENT OF PLATITUDES.

OF late there has been a boom in what we may call the pathological medical novel and now a member of the medical profession has determined to return the compliment and publish a "novel" medical work. True, he calls it the *Family Physician*, and what a delightful picture of both the family and the physician is here presented. "Woman's sphere," he says, "is not to sparkle in the realms of literature, but to shine with a clear, steady and warm light in her home, while affection glows in her eyes to the exclusion of critical hauteur, and children comprise her companions instead of books on recondite philosophy." So much for the family. When we come to the physician we are much struck by the novelty and soundness of his remarks. "Jaws," he gravely tells us, "as is well known, form a portion of the skull, and are employed in the process of mastication." Also Her Majesty Queen Anne is dead! "Jejunum is the lower portion of the small intestine." Mr. Ruskin, if we remember rightly, in "Modern Painters," says that the Greeks had a deficient colour sense, and gives as an instance, amongst others, the term "hyacinthine" as applied to hair. Our author knows all

about it. *Sub voc.* "Hair" we find: "Hair in many ways resembles a plant, as it grows from a follicle within the skin..... Its mode of growth is very similar to that of the hyacinth." We commend this book with a few errata to the notice of pure literature societies and village library committees or school boards as an exercise in grammar. Take the following: "Salads when combined with animal substances and the different varieties of fish often enable one to eat, in consequence of their palatable composition, when they might not be able to do so were the more common varieties of food presented to them." The picture of an anorexic salad is indeed touching.

DIPHTHERIA IN LONDON.

UNHAPPILY the constant decline in the death-rate from diphtheria in London witnessed since the first week in January has received a decided check. Whereas in the three succeeding weeks the deaths were respectively 34, 31, and 29, they rose last week to 45, and were 12 in excess of the corrected average. Only 1 occurred in an infant under one year of age, but 31 in the next four years of life, and 11 in young people under twenty years of age. They included 7 in Islington, 6 in Camberwell, 3 each in Mile End Old Town, Newington, and Plumstead, and 2 each in five other widely separated sanitary areas. The cases admitted to the hospitals of the Metropolitan Asylums Board were last week 76, or almost identical with those of several recent weeks; whilst the cases remaining under treatment last Saturday (519 in number) showed but little variation, having been 517, 514, and 528 on the three preceding Saturdays. In Greater London there were 12 deaths registered last week as due to diphtheria, including 5 in West Ham district.

THE EXPOSURE OF AN INFANT.

AN inquest was held by Mr. Luxmore Drew at the Fulham mortuary on Jan. 28th touching the death of the newly born male child of Florence Blunger, a domestic servant. From the evidence it appears that the girl went into residence at the house of a midwife for the purpose of being confined, and that she made arrangements for the child to be taken away to be nursed. Only two hours had elapsed from its birth when the infant was removed by the person charged with its care. The weather at the time was bitterly cold, and there is little cause for surprise at death occurring two days later. The post-mortem examination showed that the child, though small, was healthy except for the acute disease which ended its life. The lungs had been fully inflated by natural respiration, but each showed marked congestion passing into pneumonia. It has been said that "death from starvation is death by cold." In this case there was partial starvation, since very little nourishment had been taken, and in addition there was direct exposure to a low temperature. The fact of the child having been well wrapped up was no protection against the deleterious effect of admission of cold damp air to the delicate structures of the lungs, and at a time when these organs are, so to speak, in a state of physiological embarrassment, at the time of inception of respiration. To say the least, such exposure showed gross carelessness on the part of the midwife—who could not shield herself under the claim of gross ignorance—in allowing a child of such tender age to be heedlessly submitted to climatic conditions sufficient to test the strength and endurance of the most robust adult. Guided by the able and lucid address of the learned coroner, the jury forebore to bring in a verdict of manslaughter, but to their finding that death was from natural causes they added a rider to the effect that the midwife was deserving of severe censure. They expressed their "strong condemnation of the system of houses for wholesale

confinements and distribution of children being unlicensed," and urged "that all such houses and every person taking a child to nurse should be registered." We endorse every word of this presentment. Much has been done by the Legislature to protect infant life, but a consideration of the above case shows there is still urgent need for a further enactment.

NURSE OR MIDWIFE?

A CORRESPONDENT has sent us the first annual report of the Lincolnshire Nursing Association, in which a system of nursing is described as an alternative to the system of nursing with nurses of higher training, and as applicable to poor districts or villages in the country which are too poor to employ the latter class. The training "consists of three months' training in midwifery, at the end of which they pass the L.O.S. examination and receive its diploma" (*sic*); also three months' training in monthly nursing, with as much instruction and training in general sick nursing in the district as can be given in so short a time. We observe that the committee of the association recognises the entirely limited nature of the training and aptitudes of these women, and wishes to subordinate their action to the medical men of the districts in which they are employed. We do not gather that any of them have been employed by the Association as midwives, but rather surgically. Their training, such as it is, has been procured mainly by county council scholarships bestowed on selected candidates. Still, it is to be regretted that the document of the Obstetrical Society is spoken of as a "diploma." We do not propose now to discuss fully the scheme of this association, which contains some interesting and even commendable features. We only observe the report as an illustration of two things—first, the prominence of the "diploma" of the London Obstetrical Society; and, secondly, the efforts of poor districts to supply a class of women with some slight training when the more thoroughly trained nurse is an impossible luxury.

STREET SHELTERS IN RELATION TO THE POOR AND TO THE PUBLIC.

A REPORT issued last week by the Charity Organisation Society on the condition and the social and sanitary effects of street shelters in Whitechapel is of interest as a criticism upon the tendencies of this method of relief. Briefly summed up it amounts to a verdict of unqualified condemnation. The good intention of the charitable originators is admitted, but experience, it is said, has proved their whole system to be founded upon a fallacy. Due account has not been taken of the frailty of human nature. The shelters do not, we are told, become centres of improvement tending to engender self-respect and independence in their occupants. Instead of this, they have been found to promote idleness and neglect of social and domestic obligations. Those who tenant them at night pass the day in begging or equally unprofitable pursuits. The internal management falls far short of what is desirable. All manner of persons are herded together indiscriminately, and crime, dirt, and disease find among them a common home, secure from the inconvenient intrusion of the police or of sanitary inspectors. Furthermore, the shelters act as hindrances to other and more carefully administered measures of charity. Those who resort to them would under other circumstances come under the notice of parochial guardians or in contact with voluntary agencies not a whit less charitable than the shelter committees, but in their methods and purpose elevating, educative, and opposed to pauperising tendencies. The shelters do no more, in fact than their name barely indicates, unless it is to hold the pauper contented in his degradation and careless

of his duty as a member, even if a poor member, of an industrious community. A more damning indictment than this could hardly be conceived. Unless the statements contained in it should be very materially modified on further examination the free, or virtually free, shelter is no better than a nursery for social weakness and iniquity. To the absence of inspection, which is one of the most regrettable features of this system, we have already directed attention,¹ and we consider it to be absolutely essential that this anomaly should be done away with by legislation if the shelter is to enjoy even a permitted existence amongst us.

TAXATION AND THE MEDICAL PROFESSION.

THE time is coming round when the Chancellor of the Exchequer will be engaged in considering, on the one hand, how he can raise the money which he needs, and, on the other, how he can relieve the taxpayers who are entitled to his consideration. A correspondent with much force argues in favour of a reduction in the inhabited house duty paid by medical men on the ground that their house is a part of the heavy expenditure necessitated by their profession. Other classes are favoured in respect of this particular tax whose claims are not any stronger than those of the medical profession. It is not too much to hope, considering the modest proportions of medical incomes and the large deduction to be made from them for unavoidable expenses of practice and the initiatory cost of medical education, that the principle of exemption will be so stated as to apply very freely to them. There has been a disposition to regard medical men as being among the classes with comfortable incomes unaffected by the vicissitudes of commerce and earned without much labour. No mistake could be greater. Their incomes are small and precarious, and they represent an amount of labour and risk greater than that of almost any other calling. Under these circumstances we appeal to the Chancellor of the Exchequer, not for pity, but for justice.

TABES AND GENERAL PARALYSIS.

In the *Archives de Neurologie* a paper on this subject recently appeared by Dr. Chabbert, which is shortly abstracted in the *Neurologisches Centralblatt*. The relation of the two diseases is considered with special reference to the case of a woman aged forty-three, who had suffered from syphilis in her thirtieth year. In 1889 she had had severe neuralgic headaches, giddiness, and amblyopia. The difficulty in regard to vision passed off after six months. A year later she had during a period of ten days attacks of sickness lasting for one hour and a half to two hours at a time, quite irrespective of the taking of food and unassociated with pain. She experienced a few months later difficulty with both bladder and rectum, which was only temporary. She also had during twelve days sharp lightning pains in the lower extremities. Between 1891 and 1893 she was fairly well, but her sight was gradually becoming worse. After a few months symptoms of general paralysis manifested themselves—extravagant ideas, tremor of the hands, and characteristic articulatory difficulty. There was progressive failure of intelligence, weakness in the lower limbs, internal ophthalmoplegia, and blindness. Dr. Chabbert discusses the question whether the foregoing case is to be regarded as one of tabes dorsalis, followed by general paralysis, or as one of general paralysis with initial symptoms simulating tabes. The gastric crises and lightning pains would favour the former view were it not that, as he remarks, the vomiting was unaccompanied by the severe pain which usually accompanies true gastric crises, and the pains in the limbs were too brief in their duration to be regarded as true lightning pains. Further, the knee-jerks were present

all through the illness, and there was no sensory impairment. All these facts lead him to believe that in this particular case no true tabes was present, but that the symptoms which were observed in the early stages of the illness are to be regarded as early indications of general paralysis. It seems to us that a wide question like this is not to be settled by reference to a single case. That there is a close connexion between tabes dorsalis and general paralysis no one, we venture to think, who has had much experience of either disease will think of denying. If the essential lesion in tabes is to be regarded as posterior sclerosis it is also indubitable that certain cases of general paralysis have symptoms of tabes long before any unequivocal symptoms of dementia are present; and that the one disease should occasionally merge into the other is not to be wondered at if, as most authorities now agree, syphilis is to be regarded as a causal factor in each.

THE MAKING OF MENDICANTS.

WE must congratulate the council of the Charity Organisation Society upon the practical unanimity of their recent meeting for the purpose of putting a stop to charitable mendicancy, for so we desire to term the custom of sending children into the streets to beg for contributions to charitable institutions. That this practice has increased very much within the last few years no one will deny—in Piccadilly, Kensington, and Chelsea especially so, Sloane-square being a sort of focus. Boxes are rattled in the face of passers-by by children not infrequently tricked out in some fantastic garb, and the pennies of the good-natured thus obtained on behalf of charities which may be perfectly reputable or may be, for all information to the contrary that can be obtained, questionable. Our experience of this method of collection is that the sum received by the charity when collected by these means amounts to about one-third of the total collected. We are sure that any self-respecting hospital or institution which has been driven to collect money by these means would gladly welcome any way of repressing the evil, and indeed we are not sure that the repression of the practice of street collecting by the Hospital Saturday Fund might not be included in the scheme of reform.

A MODERN IMMORTAL.

NEARLY fifty years have passed since a discovery was made which was to revolutionise surgery, and not until now, except upon his tombstone, has the name of the discoverer been inscribed in any public place. At the end of last year—to be accurate, November, 1894—the State of Massachusetts placed the names of fifty-three of her most celebrated sons in the new chamber of the House of Representatives in Boston. Prominent among these is the name of Morton, to whom belongs the immortal honour of having been the first to demonstrate that prolonged anaesthesia could be safely produced by means of ether. It is a fitting coincidence that at this time Boston should be preparing to decorate her library with the Legend of the Holy Grail—a Christianised version of the old Celtic story of Ceridwen's cauldron, which offered life and freedom from care and pain to all who drank from it; and who will deny that anaesthetics are a life-prolonging draught to thousands who partake of them and that pain is robbed from the sufferers while they sleep? In some memoranda kindly sent to us by Dr. W. J. Morton of New York, is an interesting letter from the late Oliver Wendell Holmes, dated Nov. 21st, 1846, addressed to Dr. Morton, in which he says, "Everybody wants to have a hand in the great discovery." He goes on to suggest that the state produced by the new agent should be called "anaesthesia," and the adjective should be "anæsthetic." He draws special attention to the necessity for having

¹ THE LANCET, Dec. 23rd, 1893.

an appropriate name, for "the term will be repeated by the tongues of every civilised race of mankind." Morton, as is generally the case with benefactors of their species, died at an early age, worn out and in poverty.

SIR SYDNEY WATERLOW.

It is gratifying to us to see accounts of the improvement in Sir Sydney Waterlow's health. He has been somewhat seriously ill, but is said to be making gradual progress towards recovery. Sir Sydney Waterlow is identified with many causes of public and social importance, notably with the Hospital Sunday Fund and with the housing of the working classes. All who have worked with him will desire his complete restoration to health, so that he may continue to afford assistance and counsel in these great questions.

CHARGE OF MANSLAUGHTER AGAINST A MIDWIFE.

DR. DANFORD THOMAS on Tuesday last concluded an inquiry into the circumstances attending the death of Hilda Gray, aged twenty-four, of Peckwater-street, Kentish-town, from puerperal fever. She had been attended by a midwife, by name Rake, who, it is alleged, had continued to attend cases after being requested by Dr. J. F. Sykes, the medical officer of health of St. Pancras, to desist from doing so, his attention having been called to three cases of puerperal fever in patients under her charge, and subsequently to two more, and then to three more—eight in all. It transpired in the course of the inquiry that of these eight cases five had died, and Mrs. Rake was committed for trial on a charge of manslaughter. Under these circumstances we withhold all comment on a very painful case.

THE DIFFUSION OF SMALL-POX.

LAST week there was a considerable rise in the number of fresh cases of small-pox notified in London, the increase being due, however, to the rapid manner in which attacks occurred in one sanitary area—namely, Marylebone. To this parish also belonged the two deaths registered from small-pox in London during the week, one being in an unvaccinated infant under one year of age and the other in a person in the age-period five to twenty years, concerning whose state as to vaccination no information is given. The admissions to the institutions of the Metropolitan Asylums Board numbered 21, against 8, 6, and 8 in the preceding three weeks; and the total number of patients remaining under treatment on Saturday last was 51, an increase of 16 in the week. The fresh cases were 22 as compared with 7. News of a case comes from Leicester, and Smethwick and Aston Manor each had multiple attacks recorded. At Birmingham matters have taken a happy change, the new cases numbering less than half a dozen, no death being registered. During the concluding quarter of 1894 the notified cases of small-pox were 401 (as against 2 and 583 in the two preceding fourth quarters), 70 cases being notified in the fifth week of the quarter; the disease declined towards the close of the year. The deaths numbered 32 among the 401 cases, or 8 per cent., the 19 deaths among 356 vaccinated patients being equal to 5.3 per cent. of cases, and the 12 deaths among the 31 unvaccinated patients being 38.7 per cent. of those cases. It speaks well for the organisation of the health department that 395 of the cases were removed to the City Hospital. Two or three attacks occurred in Bootle and some half a dozen in Liverpool last week, no death, however, having to be chronicled. Dr. Hooper has reported to the Tooting board of guardians that in the Tooting district, to which the prevailing outbreak of small-pox has been almost entirely confined, three times and a half as many children escape vacci-

nation as compared with Liverpool proper, and that in one small locality alone no fewer than 230 unvaccinated persons had been found. The marvel is that the outbreak has been such a mild one. We trust that the area may not yet have to learn the danger of delay. In Dublin the fourth week of January witnessed a rise from 61 to 64 in the number of admissions to hospital, 73 patients being discharged and 171 remaining under treatment, in addition to 147 convalescents at Kilmaham; of 7 deaths which occurred, 3 were in vaccinated and 2 in unvaccinated persons. No statement could be made as to the two remaining. It now transpires that the corrections noted in THE LANCET of the 2nd inst. were not called for, the Registrar-General having reaffirmed the data as presented in our columns of Jan. 26th as to admissions and remaining cases. At Newry there were 21 cases in hospital at the beginning of this month, one death having occurred in January. Schools have been closed for six weeks, and hundreds of persons have secured the benefits of vaccination at the dispensary. Of the 52 deaths from small-pox in Ireland in the last quarter of 1894, only 1 (in Londonderry) occurred outside the Dublin registration district. Small-pox continues to be heard of in Edinburgh and district, 7 cases having been reported in the city in the fourth week of January and 1 death having been registered in Glasgow and in Leith respectively.

COIR FIBRE FOR SOLDIERS' BEDDING.

THE Secretary for War, when introducing the Army Estimates in the House of Commons in March, 1894, referred, among other improvements, to the issue of coir fibre bedding in place of straw bedding—a change greatly to the comfort of the soldier. He added that the change necessitated an increased charge at first, although it would probably cause a considerable saving eventually to the department. There can be little doubt that Mr. Campbell-Bannerman spoke advisedly in these respects; the use of coir fibre as a substitute for straw for bedding, in addition to its hygienic advantages, adds to the soldier's comfort and is also calculated to effect a considerable saving to the State. It appears that this subject was brought to the notice of the Surgeon-General of Her Majesty's forces in India by Brigade-Surgeon-Lieutenant-Colonel Hill Climo in 1884 and that coir bedding is, by orders of the Government of India, used for British troops serving in that country. Brigade-Surgeon-Lieutenant-Colonel Climo, impressed with the advantages—hygienic and financial—of coir as a substitute for straw, subsequently, we believe, brought the subject to the notice of the military and War Office authorities of this country, and the use of coir for soldiers' bedding was experimentally tried and tested for some time at Aldershot, with such a measure of practical success that it was adopted. The officer who so zealously interested himself in getting this reform introduced into the army has since retired from the service. Assuming what we have said to be a correct statement of the facts, we should like to know whether his services in this direction have ever obtained any recognition or reward.

"THE NEW STREET DANGER."

ACCIDENTS in connexion with underground electric light mains are reported from Rochester, Eastbourne, and Dover, and on the 2nd inst. there occurred the more serious disaster at Southwark-bridge. In this last instance it appears that coal gas escaping from a main under the carriage way had found a path into the electric light culvert under the footway, and becoming ignited the explosion had blown up the pavement, the covers of four junction boxes being "shot up some distance into the air." Five persons were injured. One of these "suffered from shock," and others from bruises and wounds. This is, we believe, the sixth accident of the

kind which has occurred in the City during the past two years, and in one case, at least, the vestry were advised of the danger beforehand and of the method of remedy. A time will probably come when electrical engineers will find themselves in practical agreement as to the best and safest systems of laying underground electric lighting mains, but in the meantime existing systems have to be dealt with. It is evident that underground electric main culverts and "boxes" constitute in some instances reservoirs of considerable capacity for an accumulation of escaping coal gas, which, unmolested and ever increasing, only awaits the electric spark or arc or red-hot conductor, or the lamp of the workman or a discarded match, to determine its explosion. The means of minimising this kind of danger by ventilation, drainage, insulation, and attention to the construction of street boxes with a view to the reduction as far as possible in their capacity, are sufficiently well known. And searching inquiry should follow all such accidents. But it may also be suggested that inspection might materially diminish the frequency of their occurrence.

A HEALTH MANUAL FOR THE PEOPLE.

THE Imperial Health Institute of Berlin, which has done so much to advance sanitary science in its highest and widest sense, has lately issued a small manual of health for popular use and at a popular price (it is only one mark) under the title of "Gesundheitsbüchlein." Within its 254 pages it comprises a brief account of the structure and functions of the body; it then deals with individual or personal hygiene, in respect to air, water, soil, food, clothing, dwelling, work, and rest. Next comes what may be called social hygiene, and a fourth section deals with the dangers to health from external influences, as climate and weather, infection, and accidents. An appendix gives some counsel on the care of the sick. Dr. Gärtner, who in the *Fortschritte der Medicin*, notices appreciatively this new departure of the State Department interested with the care of the public health, points out that in some matters the book hardly speaks positively enough, although he fully recognises that a work issued from so authoritative a source must needs be cautiously worded.

NINETEENTH-CENTURY VAPOURS.

In the current number of the *Contemporary Review* there is an interesting article by Professor Clifford Allbutt, which we recommend to our readers on account of its cheery optimism. All of us who read have been made much aware of late of the presence among us of a noisy if small band of Jeremiahs, who tell us persistently that the world is worn out; that madness and neurotic diseases increase day by day; that all the old safeguards of morality and religion are one by one being broken through; that, in short, nothing and no one is any good. The cry is a very old one, and none the more true for that; but its supporters are many of them eloquent with voice and pen, and any opinions shouted loudly enough are sure to command a hearing. But, we repeat, it is not true, and is made the excuse for a good deal of meddlesomeness. We are living, in fact, in an island of Polupragmosyne, where, as Charles Kingsley says, "everyone knows his neighbour's business better than his own, and where all people set on the wayfarer to show him that he does not know his way and to demonstrate incontestably that, whichever way he is going, he is going wrong." Modern life, with all its complexities, is of course a very different thing to the simple existence led by our forefathers, but there is no proof that we are not fully equal to the divers strains. There will always be those who fall by the way, but this is not a calamity peculiar to our generation, and for one of us that falls from over brain work surely two of our ancestors were wont to succumb to the hard work of idleness. It is, to quote Professor Allbutt, "rather the conditions under which

work is done than the work itself which is mischievous." "The secret of health," he goes on to say, "and the secret of virtue, which is the health of the mind, are happily one, and it lies in the concern of the active intellect with the sensations which bear upon us without." The healthy exercise of the mind is to the brain—the heart of the nervous system—what bodily exercise is to the bodily heart, honestly done work demands as its complement honestly taken pleasure, and neither if not abused can harm either body or mind.

DEATH AND HIS BROTHER SLEEP.

It is difficult to see what purpose, either scientific or pleasurable, can be served by "experiments" like that now being carried on at the Westminster Aquarium. The possibility of human beings existing for days in a cataleptic or trance state has, we believe, been proved over and over again. But if this were not so, if the Aquarium were exhibiting for the consideration of laymen a real medical curiosity, it would still be altogether unfitting that Dr. Forbes Winslow, a Member of the Royal College of Physicians of London, should lend himself to the furthering of such a show. He is reported in the *Times* of Feb. 2nd as saying that there was no recorded instance of a person sinking while in a hypnotic trance. Now, just such a death occurred in Hungary last year, the case being that of a girl to whom it was "suggested" that she had phthisis, and the tragic affair was made the subject of more than one comment in our columns. Did not Colonel Townsend also—we have not the reference at hand—die in one of his self-produced trances? Dr. Forbes Winslow appears to us to have not only taken upon himself an unwise and undignified task, but, if he has been correctly reported, to have disseminated wrong information. The temperature of the first of the Aquarium performers fell to 95.4° F. after being some twenty-four hours in his unnatural condition, whereupon he was awakened, and no one will say that it was not the wisest course to pursue. Since writing the above we have received a letter from Dr. Forbes Winslow, and also one from Dr. Norman Kerr, which are published in another column; while we learn that a second subject who was placed under hypnotic influence last Monday has showed signs of a flagging circulation.

HOSPITAL SMALL-POX INFECTION.

DR. CHARLES PORTER, the medical officer of health of Stockport, has placed on record two curious and interesting cases in which the infection of small-pox was received in the ward in the borough hospital in 1893 under very exceptional circumstances. In the first instance, a child admitted to the scarlet fever ward in January was found to have the papular eruption of small-pox a month later. Minute investigation failed to discover the cause of infection, until it was found that a cat, secretly kept by an attendant in the ward, had visited the small-pox pavilion. Needless to say that the "harmless, necessary cat" was expelled at once and proper measures of disinfection and sulphur fumigation were taken in the ward. The second instance occurred in the same scarlet fever pavilion a fortnight later, and its relation to the small-pox ward was discovered quite accidentally. Dr. Porter traced a smell of sulphur in the latter ward, then empty, at the end nearest the scarlet fever pavilion, and investigation led to finding an unsuspected subway between the two wards, by means of the tunnel along which the heating pipes were carried. The higher temperature of the fever ward had, says Dr. Porter, evidently drawn in air from the small-pox ward. One or two points, however, do not seem to us to be quite clear as to the cause or causes of these two cases of small-pox. First of all, nothing is said as to the condition of the patients as to vaccination. And

next, granted the source of the first case, might not the second have derived infection therefrom, nothing being said, however, as to the date of admission of this second case? And, again, may not both cases have derived their infection aurally? But at any rate the hypotheses advanced are of interest, especially in view of the fact that after elimination of the supposed causes of the disease no further secondary cases of small-pox occurred in the hospital. Still, we are glad to find Dr. Porter, in another portion of his annual report, advocating separate hospital accommodation for small-pox.

THE DANGERS OF CIRCUMCISION.

SOME interesting letters on the risks of circumcision appear in the *New York Medical Record* of Jan. 26th. They do not deal with the rite as such, but with certain dangers incidental to its careless or unskilful performance. One question is whether it can be performed as safely by the Jewish mohel as by a surgeon acquainted with all the details of antisepticism, and the argument of the writers is strongly in favour of its being done by the educated surgeon. Dr. Henry Levien has examined the reports of the Board of Health and found circumcision reported as a cause of death sixty-seven times between 1881 and 1894 inclusive. He attributes the greater mortality since 1881 to the great increase in the Hebrew population since that date. Dr. Martin Schwartz denies that the mohel is an expert in the sense that the physician is, and says he has seen various mutilations as a result of his operation, such as cutting off part of the glans penis, removal of too much foreskin, and in one case the removal of a piece of the scrotum the size of a half-dollar. The practitioners of the east side of New York, he says, are frequently called to hæmorrhage in such cases. The mohel knows very little of sepsis, and ties up the wound with dirty rag. Neither his hands nor instruments are antiseptic, and he is in the habit of sucking the wound with his mouth, with the risk of contact with any carious teeth or syphilitic or other sores of the mouth. That circumcision by the mohel does not figure more frequently as a cause of death is attributed to the fact that if complications arise the physician is called in and saves the patient. It must be admitted that in this country we seldom hear of such accidents, but the questions raised are serious ones and worthy the consideration even of those who regard the operation as a religious duty.

THE Lord Mayor will take the chair in the Egyptian Hall at the Mansion House on Wednesday afternoon next, Feb. 13th, at 3 P.M., at a meeting to be held in aid of the special appeal fund for St. Thomas's Hospital. As we have already announced, his Lordship will on this occasion be supported by H.R.H. the Duke of Connaught, the President of the hospital; and among others who will be present we may mention the Bishop of Rochester, Sir William MacCormac (consulting surgeon to the hospital), Sir Stuart Knill, Sir Albert Rolit, Dr. W. M. Ord (senior physician to the hospital), and Mr. Mackellar (senior surgeon to the hospital).

DR. MANSON will lay the results of his work on the Malaria Parasite before the Hunterian Society at the London Institution on Wednesday next, at 8.30 P.M. This communication will form the Annual Oration for 1895, and all members of the profession are at liberty to attend.

SIR RALPH THOMPSON, K.C.B., has been appointed Chairman of the Weekly Board of the Middlesex Hospital, W., in the room of Lord Sandhurst.

A SPECIAL MEETING of the council of the Charity Organisation Society will be held on Monday next, Feb. 11th, at the Hotel Victoria, Northumberland-avenue, at 3 P.M. Mr. W. Bousfield, chairman of the council of the society, will preside, and Colonel Montefiore will read a paper on the Need of a Central Hospital Board in London, with special reference to the promotion of uniformity in the system of admission to hospitals. Sir John Erichsen and Dr. W. M. Ord are announced to take part in the discussion.

DIFFICULTIES UNDER THE INFECTIOUS DISEASE (NOTIFICATION) ACT.

III.¹

3. Action to be taken as the Result of the Visit.

THE purport of the visit to be paid by the medical officer of health, when he regards the information conveyed to him as involving an "outbreak of any contagious, infectious, or epidemic disease of a dangerous character," is very clearly set out in the official Order. It is that he shall "inquire into the causes and circumstances of such outbreak, and in case he is not satisfied that all due precautions are being taken he shall advise the persons competent to act as to the measures which may appear to him to be required to prevent the extension of the disease, and to take such measures for the prevention of disease as he is legally authorised to take under any statute in force in the district or by any resolution of the sanitary authority."

One of the first objects, then, is that the medical officer of health shall determine whether or not he is satisfied that all due precautions are being taken which are required to prevent extension of the disease, and he is to advise accordingly. Now it is evident that he cannot in a number of instances form a proper judgment as to this without some sort of communication with the medical practitioner in attendance on the case; and it is doubtless for this reason that the Local Government Board have so often suggested that there should be harmonious coöperation in such matters. Thus, they wrote in one case: "It is of the utmost importance that he (the medical officer of health) should act in harmony with the medical attendants of the sick, so as to obtain from them the valuable assistance which they can afford to him in his work." In another case they wrote thus: "They may observe, however, when the patient is under the charge of a private medical practitioner the medical officer of health should, no doubt as a general rule, confer with such practitioner in considering what precautions should be taken to prevent the spread of the disease, but that where conference could not be had it would not be right to delay local inquiry into the matter." We must admit that in large urban centres where the poorer and the labouring classes are thickly congregated there might be much difficulty in complete compliance with this injunction; but, on the other hand, we are convinced that in such cases medical practitioners will leniently view any departure from it, especially if they know, from the general action of the health officer, that he makes it a point, where practicable, of securing the harmonious coöperation indicated. Indeed, many medical practitioners gladly welcome the advent of the sanitary officials with their printed forms as to precautions, their disinfectants, &c.; and in well-organised urban and other districts it is by no means always necessary that the action to be taken should involve any other visit, at least in the first instance, than that of the sanitary inspector. And there will be many cases, where a visit from the medical officer of health is not needed, when direct communication

¹ Parts I. and II. were published in THE LANCET of Jan. 19th and Jan. 26th, 1895, respectively.

as to a case between him and the practitioner in attendance will not be requisite.

Sometimes difficulty arises as to whether measures of disinfection and the like ordered by a practitioner are sufficient. The responsibility as to these measures, and as to school and other attendances of members of the infected family or household, rests primarily with the medical officer of health; and as a rule his judgment should be accepted as final. But if a difference of opinion does arise such a case will, more than any other, be one where the two medical men should if practicable meet, with a view to that harmonious action so essential under the circumstances.

There have been occasions when a medical officer of health has felt it his duty at once to advise removal of a patient, concerning whom he has received a notification, to an isolation hospital, and much irritation has been occasioned when a medical practitioner has found that, unknown to him, preparations have been made for the removal of his patient or else that the removal has actually been effected at the time when he first hears of it. Recalling some of the cases which have come under our notice we are bound to admit that it is extremely difficult to lay down any rule as to this which shall suffice for application in all instances. In a widely scattered rural district where a medical officer of health finds a patient suffering from infectious disease under circumstances which he feels confident are certain to lead to the immediate spread of infection, and so call for the closure of the schools and the consequent suspension of elementary education; or where he finds that the only disposal of the infected excreta must involve risk to water-supplies, public or other, it must be clear that he has a duty towards the public to act promptly and not to delay action—the whole value of which will depend in its being immediate—merely in order to observe certain professional courtesies. In such a case personal communication before action with the medical attendant might ensure mischievous delay, and he could hardly be expected to do more than inform the medical practitioner as speedily as possible of the instant action which he had found it imperative to take; but, speaking generally of such cases, it might be well to limit immediate action to those patients who are so circumstanced that compulsory removal to hospital could and ought to be enforced. This means that, to use the terms of Section 124 of the Public Health Act, 1875, the patient would be either "without proper lodging and accommodation," or "in a room occupied by more than one family," or "on board any ship or vessel." In most other cases—and, indeed, in all cases where it is practicable—no such action should be taken except after an endeavour to secure the coöperation of the medical practitioner in question.

4. Cases where the Diagnosis is Matter of Doubt.

Certificates of notification are at times received by medical officers of health who doubt the correctness of the diagnosis. The cases of this class that have given rise to most trouble are those in which the medical officer of health has reason to doubt whether the patient to whom the notification relates has either any infectious disease at all or is suffering from one that is notifiable under the statute. The case of certificates deemed to be fraudulent has already been dealt with, and we only refer here to cases where the diagnosis is regarded as incorrect, and where no wrong motives can be ascribed to the notifier. The action which we would strongly urge in such cases is that the medical officer of health should always act on the assumption that the certificate is correct even if he doubts it. Fortunately, many leading medical officers of health act on this assumption as a matter of practice, feeling that any loss of time or money which results from processes of cleansing, disinfection, &c., which may turn out to be unnecessary, bear no comparison in importance with the necessity of avoiding friction between the public health department and the local

members of the medical profession. The Local Government Board have evidently adopted the same view. Thus, writing on Jan. 28th, 1891, to a metropolitan vestry clerk, that Board said: "The Board gather from the report that the medical officer of health regards it as incumbent upon him to visit each patient and verify by personal examination the accuracy of the certifying practitioner's diagnosis. The Board, however, do not consider that either the Act itself or any Order of the Board imposes any such obligation on the medical officer of health, and it appears to the Board that it would usually be very inexpedient that he should undertake a personal diagnosis of a case notified to him for the purpose of testing the accuracy of the certificate, unless he has reason to believe that the medical practitioner is not acting in good faith. In the present case there is apparently no allegation of bad faith. The question seems to be one of differing diagnoses only, and this in itself is, in the Board's opinion, not sufficient to warrant the rejection of the certificate of the medical attendant." And in a subsequent letter, written in 1891 to a provincial town clerk, the Local Government Board say: "I am to state in reply to the inquiry with which your letter concludes that unless in the cases to which you refer the sanitary authority satisfy themselves that they have sufficient grounds for doubting the good faith of the certifying practitioner the authority should, in the Board's opinion, pay the fees for the certificates."

These two letters set out that which is the habitual practice of most medical officers of health, and it would be well that the advice which they give should be uniformly adopted. In a district where the diagnosis of a case was recently questioned the medical practitioner contended that he, as a bedside practitioner, was more competent to form an opinion than the medical officer of health, who had early in life abandoned clinical work and had for a series of years devoted himself exclusively to public health duties. This is a consideration which is worth remembering, and it incidentally raises the extremely important question as to how far it is for the public benefit that medical officers of health should altogether sever their connexion with clinical and bedside work. Some, indeed, contend that, whilst medical officers of health may in a number of districts be properly prohibited from following general practice, they ought to be encouraged to hold appointments, as, for example, in the capacity of medical officers to institutions, where they would remain in touch with clinical work. But however this may be, we only refer to it here as indicating an additional reason why the medical officer of health should accept certificates without attempting to revise the diagnosis, even where he may think that diagnosis to have been made in error.

(To be continued.)

ARMY MEDICAL SCHOOL, NETLEY.

TERMINATION OF THE SIXTY-NINTH SESSION.

THE sixty-ninth session of the Army Medical School was brought to a close on Thursday, January 31st, when the prizes were presented and an address was delivered by Mr. W. H. Russell, LL.D., in the presence of the staff of the Royal Victoria Hospital and a distinguished company.

Surgeon-Major-General C. H. Giraud, Principal Medical Officer, Netley, opened the proceedings, and referred with regret to the unavoidable absence of the Director-General, Sir William Mackinnon, K.C.B., and of Sir Joseph Fayrer, K.C.S.I. He called on Brigade-Surgeon-Lieutenant-Colonel J. L. Notter, Secretary to the Senate of the School, to read the results of the examination. Professor J. Lane Notter then read out the official lists, of which the following is a summary:—

British Medical Service.

List of Surgeons on Probation of the Medical Staff of the British Army who were successful at both the London and

Netley examinations. The prizes are awarded for marks gained in the special subjects taught at the Army Medical School.—The final positions of these gentlemen are determined by the marks gained in London added to those gained at Netley, and the combined numbers are accordingly shown in the list which follows:—

Jan. 31st, 1895.		Combined marks.	
*Harrison, W. S.	3652	Staddon, H. E.	3533
Howell, H. A. L.	4931	Whitehead, J. H.	3577
†Lawson, D.	4556	Murison, J. A.	3537
Steel, E. B.	4316	Tomlinson, L. P.	3746
Proffit, C. W.	4251	Perry, S. J. C. P.	3514
Kiddle, F.	4183	Heaton, A. F.	3552

* Gained the De Chaumont Prize in Hygiene and the Martin Memorial Medal.

† Gained the Montefiore Second Prize in Surgery.

Indian Medical Service.

List of Surgeons on Probation of the Indian Medical Service who were successful at both the London and Netley examinations.—The prizes are awarded for marks gained in the special subjects taught at the Army Medical School. The final positions of these gentlemen are determined by the marks gained in London added to those gained at Netley, and the combined numbers are accordingly shown in the list which follows:—

Jan. 31st, 1895.		Combined marks.	
*Milne, C. J.	5635	Morgan, E. J.	4438
Stevens, A. F.	4971	Ward, A. E. F.	4394
†Bensley, C. H.	4845	Carr, W.	4313
Watling, F. H.	4768	Hamilton, J. A.	4252
†Evans, S.	4621	McDonald, J. H.	3745
McMillan, J. D.	4534	Wall, F.	3822
Gwyther, A.	4506	Matthew, C. M.	3758

* Gained the Herbert Prize of £20, the Montefiore Medal and prize of 20 guineas, and the Maclean Prize for Clinical and Ward Work.

† Gained the Parkes Memorial Medal.

‡ Gained the Pathology Prize presented by Sir W. Mackinnon, K.C.B.

Dr. Russell afterwards distributed the prizes, and at the conclusion of the interesting ceremony he delivered a very excellent address, full of incidents of the Crimean War. He said he could honestly say that he was not accustomed to addressing public gatherings, and when the request was sent to him to present the prizes on that occasion, he did not see any special fitness in asking him to perform a ceremony which had been discharged by so many eminent men in that hall—except one, perhaps, and that was that it had been his fortune, good or bad he knew not, to see more of the work of medical officers in the field than perhaps any of his predecessors, no matter who they might be. He had had to follow armies in no fewer than nine campaigns, and following an army was about the most painful duty that could fall to any man. The Crown Prince of Germany observed after the great action outside Paris, when he noticed the surgeons attending to the wounded, "God help those poor fellows." He (the speaker) thought the Prince was referring to the wounded, but it transpired that he was speaking of the surgeons, who had commenced their work after the soldiers had done theirs. He was very much struck with the remark. The surgeons had been through a long and laborious march, and on that particular day they had covered a distance of nearly fourteen miles. It frequently happened, except in the case of standing camps, that the surgeons had to commence their work when the soldiers' work was over, and it was beyond all doubt the most trying and painful duty that any man could perform—at least, it used to be so, when, without proper apparatus and assistance, the surgeons were left to manage a large number of wounded people on the field of battle. Notwithstanding what the surgeons were sometimes called upon to do, and the very little consideration paid to them, he had never known an instance in any army in which a medical officer had deserted his post or refused to go on with his work. More than that, until late years he had never known an instance in which any general ever mentioned the name of a medical officer in a despatch. It was unknown in the English army. The Principal Medical Officer forwarded his observations to the General-in-Chief, and the General-in-Chief sent them as an appendix to his report. The only exception which he could remember was the case of an assistant-surgeon at the battle of Inkerman, who rallied a few men when the Guards were broken and the Duke of Cambridge was in danger of being taken, and thus saved the latter's life and the colours of the Guards.

It was well that his name should be known—it was that of Assistant-Surgeon Wilson. His name was mentioned in Lord Raglan's despatch, in which it was stated that the Duke of Cambridge recommended him to notice for his gallant conduct. He hoped now that military appellations had been accorded to the medical officers of the army they would be thought worthy of mention with the combatant officers, whose work they had been trying to improve upon. It was a very desirable thing, and he hoped it would be recognised. He thought that a surgeon who rendered conspicuous service was fully entitled to every rank and honour which they could confer upon him. There were surgeons who had spent their lives for their country's benefit who had gone down without comparatively any reward or recognition, but he believed there was a good time coming. There were those who desired to see a special "order" instituted for medical officers, but he considered this to be unnecessary and undesirable, as all the orders, both military and civil, were open to medical men. The names of the professors of the school were a guarantee of the excellence of the instruction imparted to the surgeons-on-probation. There was a glorious career open to them. He considered there was nothing more ennobling than to fight in the cause of their country the most terrible enemies of mankind. Pope had said that the proper study of mankind was man, and surely the proper study for a medical practitioner was man, and in the Army Medical School they were taught how best to study the different diseases and their remedies. In 1854 he first made the acquaintance of two gentlemen whose names they knew and honoured, and he made their acquaintance not on the field of battle exactly, but certainly on the field of bloodshed, on the plateau before Sebastopol. He meant Sir Thomas Longmore and Sir William Mackinnon. It might be new to them to know that Sir William Mackinnon at one time wielded the claymore. He was seized with military ardour when he was assistant-surgeon, he believed, to the 93rd, and he received an ensigncy. Immediately after the defeat of the Russian cavalry at Balacava by the "Thin Red Line," Sir Colin Campbell approached Sir William Mackinnon and said, "I think you would be more deadly with the lance than the sword." Mackinnon, not finding any chance of more "Thin Red Line" work, went back to the profession of which he was now the chief and honoured ornament. He hoped Sir William Mackinnon would not be angry with him for telling the story. He only regretted he was not present to hear it. He need not say a word about Alexander, Muir, Ross, Tyse, Fraser, and a long roll of medical officers in the Crimea who were crushed under the weight of obloquy for what they could not help. They could not make bricks without straw, and these men were called upon to do what no man could do—to save the lives of those who were perishing from hunger, cold, want of medicine, clothing, and everything necessary to keep men alive; but they struggled on most nobly, and there was not a single instance of any neglect to be recorded on the part of any medical officer in the Crimea. He should not say much to them about their duties. He believed they knew them better than he could tell them, and judging from the work of their predecessors, all he should say was, "Do as well as they did." When Dr. Andrew Smith was ordered to prepare for the Crimean expedition an adequate medical staff and stores, he replied that neither he nor his officers knew what would be necessary for such a campaign, and on referring to the medical memoranda at the War Office, he found nothing but a list of a few officers who served in the Peninsular War. As to any records, with the exception of Sir John McGregor's notes he had nothing to guide him with regard to his arduous duties. Now all was changed. We live in better times, when the Medical Department is responsible for all arrangement. Over 18,000 men died in the Crimea apart from those killed in battle, and of that number 1700 died from wounds and 17,000 from diseases. That showed the work the medical men had to do, and the work they could not do as well. When Sidney Herbert established the Royal Victoria Hospital after the Crimean War, he had to create a military school to give them the first idea how to deal with an army, not only in war, but in peace. He regretted the absence of Sir Joseph Fayrer, whose name was associated with the siege of Lucknow, as he would have been able to say a great deal more than he could. He had received a letter from Sir Thomas Longmore, who regretted that the state of his health would not permit of his presence that day. Sir Thomas Longmore begged to bear his testimony to the substantial service rendered to the Army Medical School by Sir Joseph Fayrer, who had always earnestly endeavoured to promote its welfare.

in every direction. By his ceasing to be a member of the Senate, the school had sustained a serious loss. He had been present at most of the prize distributions, and often came down from London at great inconvenience to himself in order to be in attendance. The extent of his services to the school was beyond valuation and known but to few. Of those present at the inauguration of the school by Sidney Herbert in 1860, he (Sir Thomas Longmore) was the sole survivor. He was deeply impressed with the importance of the school, and should feel ungrateful if he did not make an acknowledgment of the debt that he and all interested in the school owed to Sir Joseph Fayrer. Dr. Russell then proceeded to say he entertained the greatest admiration for the services rendered by army surgeons, and if any of them liked to see an affecting memorial to their predecessors, when they visited Constantinople, let them go across to Scutari, where they would see row after row of monuments erected to the memory of surgeons who fell nobly on the field of battle. He was very thankful to them for the kind way they had listened to him, and he wished them every success in their future careers.

Surgeon-General Maclean also briefly addressed the young officers. He asked them to remember that although they belonged in name to two services, yet he hoped that they would regard themselves as one body; they had been messmates for four months, and he hoped no petty service prejudices or differences would ever come between them. They should be one body in thought, for they served one Royal Mistress. He said the services Dr. Russell rendered to his country in the Crimean campaign would never be forgotten. He wished the young officers a successful, happy, honourable, and useful career.

The Chairman then thanked Dr. Russell for presenting the prize, and the proceedings terminated.

ARGON.

A MEETING of the Royal Society was held in the theatre of the London University on Thursday, Jan. 31st, to discuss a paper on "Argon, a New Constituent of the Atmosphere," by Lord Rayleigh, secretary of the Royal Society, and Professor William Ramsay, F.R.S. Lord Kelvin, D.C.L., LL.D., presided.

Professor RAMSAY, who communicated the paper, speaking with reference to the density of nitrogen, said that it has already been shown that nitrogen extracted from chemical compounds is about $\frac{1}{2}$ per cent. lighter than atmospheric nitrogen. He detailed various experiments that have been made which show that nitrogen prepared from magnesium nitride, obtained by passing "atmospheric" nitrogen over red-hot magnesium, has the density of "chemical" nitrogen, and that also ammonium chloride prepared from magnesium nitride contains practically the same percentage of chlorine as pure ammonium chloride. It may therefore be concluded that red-hot magnesium withdraws from "atmospheric nitrogen" no substance other than nitrogen capable of forming a basic compound with hydrogen. Professor Ramsay next dealt with the reasons for suspecting a hitherto undiscovered constituent in air, remarking that the work of Cavendish on the composition of the air in a great measure anticipated the present discovery when, in a paper published in the Philosophical Transactions of 1788, he expressed doubt as to whether phlogisticated air was the simple body it was thought to be, and went on to say, "If there is any part of the phlogisticated air of our atmosphere which differs from the rest and cannot be reduced to nitrous acid, we may safely conclude that it is not more than $\frac{1}{100}$ part of the whole." This residue, said Professor Ramsay, is not improbable contained the new gas called argon. To prepare argon on a large scale air is freed from oxygen by means of red-hot copper. The residue is then passed over red-hot copper in order to remove all traces of oxygen; the issuing gas is then dried by passage over soda-lime and phosphorous pentoxide. It then enters a combustion-tube packed tightly with magnesium turnings, and heated to redness. Having collected the residue from 100 or 150 litres of atmospheric nitrogen, which may amount to 4 or 5 litres, it is transferred to a small gas-holder connected with an apparatus whereby, by means of a species of a self-acting Sprengel's pump, the gas is caused to circulate through a tube half filled with copper and half with copper oxide; it then traverses a tube half filled with soda-lime and half with phosphorous pentoxide; it then passes a reservoir of

about 300 c.c. capacity, from which, by raising a mercury reservoir, it can be expelled into a small gas-holder. Next it passes through a tube containing magnesium turnings heated to bright redness. The gas is thus freed from any possible contamination with oxygen, hydrogen, or hydrocarbons, and nitrogen is gradually absorbed. As the amount of gas in the tubes and reservoir diminishes in volume it draws fresh supplies from the gas-holder, and, finally, the circulating system is full of argon in a pure state. At present all attempts to induce argon to combine have proved abortive. The presence of argon in the atmosphere, however, is proved on many lines, and the probable nature of the gas, or mixture of gases, remains to be discussed. From Avogadro's law the density of a gas is half its molecular weight, and the density of argon being approximately 20, its molecular weight must be 40. Some interesting remarks with reference to the place of argon in Mendeleef's table concluded Lord Rayleigh and Professor Ramsay's brilliant paper.

Professor CROOKES, F.R.S., then read a paper on the Spectra of Argon, and Professor RAMSAY communicated a paper by Dr. K. Olazewski on the Liquefaction and Solidification of Argon.

Professor ARMSTRONG (President of the Chemical Society) said everyone would gladly join in the chorus of approbation which had been started by Mr. Crookes. On behalf of the chemist he wished to say that he felt especially indebted on this occasion to Lord Rayleigh and Professor Ramsay, not only on account of the extreme importance of the information they had given, but more particularly on account of the example they had set. The case for the existence of the new constituent was undoubtedly a very strong one, but it had not been so logically brought forward as it might have been. However, it was quite clear that there was a very sound body of evidence that made it certain that there was in the atmosphere a constituent that had long been overlooked. The paper would no doubt meet with considerable criticism throughout the world, but there was not the least doubt that their would soon be abundant confirmation of the correctness of the discovery. Apart from the facts brought forward, there was what he might call a widely speculative portion of the subject, and in dealing with the probable nature of this new element the extraordinary properties possessed by this gas had not been sufficiently taken into account. Nitrogen was a very inert form of matter, and its nature derived from its study in the atmosphere is of an altogether wrong character. If anything at all could be judged from the properties which argon is known to possess it is like nitrogen, but more so. It was quite likely that the two atoms existed so firmly connected with each other as to make it impossible for them to interfere or to take notice of anything outside them. There was a good deal to justify a view of this kind. Spectroscopic evidence did not appear to justify the conclusion that argon was a mixture of two gases. Argon had fewer affinities for nitrogen than any other substance, and there was a difficulty in placing it in Mendeleef's table.

Professor RÜCKER (President of the Physical Society) said it was extremely important to distinguish between the various points of doubt and the certain fact that beyond question a new constituent of the atmosphere had been discovered. It seemed to him that one of the most interesting results arrived at from a physical point of view was the fact that the gas was monatomic. It was necessary that the atom of argon should be considered spherical in order that its specific ratio of heat might be obtained. Whatever the difficulty might be of placing it in the periodic table, Mendeleef's law was only empirical, and did not stand on the same footing as the great mechanical generalisations which were the foundation of science.

Professor ROBERTS AUSTEN referred to the possible bearing of argon on the Bessemer steel process.

Lord RAYLEIGH said that the difficulties connected with the present investigation were extremely great. Every experiment took about ten days or a fortnight to complete, and consequently no time was left to determine by experiment many doubtful points it was desirable to clear up. This specially applied to the question of densities, and consequently they were not so satisfactorily elaborated as one could wish. The molecule behaved as a whole as if it were monatomic. Mercury gas was the only other substance which presented a similar property.

Lord KELVIN congratulated the authors of the paper on their brilliant success, and the discussion terminated.

THE CASE OF SHENTON V. SMITH: THE RESULT OF ANOTHER PETITION OF RIGHT.

ON Saturday last the Judicial Committee of the Privy Council gave judgment in the appeal of the Government of Western Australia (in the person of their Colonial Secretary) from a decision of the Supreme Court of that colony upholding a verdict and judgment for £200 obtained by Mr. Henry Lionel Smith, M.R.C.P. Irel., the respondent in the present appeal, for unreasonable dismissal from the public service. In 1887 Mr. Smith received the post of acting medical officer at Albany. In the following year events happened during the transfer of the Albany Colonial Hospital to new buildings which resulted in the death of a patient suffering from enteric fever, the immediate cause of death being, as was alleged, exposure to cold. For this death a coroner's jury of three persons attached blame to Mr. Smith, and the Government dismissed him, an order being passed on July 9th, 1888, informing him that his tenure would cease at the end of the year. Mr. Smith proved that he was not responsible for the mishap, and that the act of the workmen which led to the exposure of the patient to cold was done in his absence and without his authority, and the Government allowed an appeal to the Secretary of State, who upheld the Governor's decision. Thereupon Mr. Smith entered a petition of right, with the Colonial Secretary as defendant. In this trial the jury disagreed, but in a subsequent trial they found for the plaintiff, with £200 damages for wrongful dismissal. On the further consideration of whether the plaintiff had or had not been wrongfully dismissed the court were divided, so that the original verdict remained undisturbed. In an appeal from this before the Judicial Committee of the Privy Council on Feb. 2nd, 1895, the court ordered that judgment be entered for the appellant (the Government of West Australia), but without costs in regard to the litigation in Australia. It would appear, therefore, that colonial civil servants holding acting appointments can be dismissed at any moment by the Government without any reason being assigned, and that the regulations are of no value as protection to them; for Lord Ripon, in his reply to a memorial of a Parliamentary Committee, has said that the regulations do not apply to anyone holding acting commissions, and that the Governor can terminate all such appointments without notice and without assigning any cause. In this case Mr. Smith finds himself lying under the stigma of being a constructive murderer, and is in addition practically ruined; all this misery arising from the ill-considered judgment of a coroner's jury of three men probably entirely ignorant of medicine and incapable of forming a right judgment upon scientific subjects. We await with curiosity and a painful sense of anxiety the steps that it may please Imperial Parliament—regardless of politics—to take to recompense Mr. Smith for wasting eight years of his life, and allowing him to be pursued with all the legal machinery at the disposal of a Government with a view to fixing indelibly upon him the stain of ill-behaviour of which all who know the facts recognise that he was entirely guiltless.

A FRESH OUTBREAK OF SMALL-POX IN TOXTETH PARK, LIVERPOOL.

At the last meeting of the Health Committee Dr. Hope, the medical officer of health, alluding to the charge of neglecting to notify a case of small-pox, stated that owing to the deception practised the young man was going about the city for a fortnight spreading the infection everywhere. This case afforded an illustration of the difficulty they had in tracing such cases and carrying out their duties under the Act. He (Dr. Hope) had the case reported to him by means of an anonymous note. The guardians of the township of Toxteth Park recently requested the Health Committee to inform their board whether there were any conditions which may contribute to the prevalence of small-pox and other diseases in the district now affected by small-pox. In consequence of this request Dr. Hope was asked to

report and sent a most carefully prepared and elaborate report, of which the following are extracts:—

"The health committee have approved at great cost of precautionary measures of a stringent character, as Liverpool is particularly liable to the importation of sickness; and it is by no means infrequent that small-pox is introduced either overland or by sea. Up till comparatively recent years several matters relating to the prevention of disease were dealt with by the Poor-law authorities, but with one notable exception the whole of these matters now fall within the province of the sanitary authorities. The exception in question is vaccination, which constitutes one extremely important factor, perhaps the most important, in the prevention of small-pox. The present outbreak in the Toxteth district, so far as could be ascertained, had its origin in the introduction of the disease by tramps from the Yorkshire district. Infected persons were found by officers of the Health Committee in the more squalid parts of the district and it was apparent that there was an undue proportion of unvaccinated persons in that district. The medical officer of health consequently called the attention of the vaccination officer on Sept. 19th to the gravity of the circumstance and the guardians caused the district to be placarded with vaccination notices and provided some additional assistance temporarily for the visiting officer.

"The guardians have no doubt experienced difficulty in discovering and securing the vaccination of many of the young children of the shifting population of the lower districts, but their efforts have not been rewarded with the same measures which have attended those, for example, of the select vestry of the parish of Liverpool. Thus, according to the last published annual returns of the Local Government Board the number of children born during the two years referred to and not finally accounted for as regards vaccination are about three times and a half as numerous in the Toxteth Park district as they are in the parish of Liverpool. The difficulty encountered in discovering the unvaccinated children is not insuperable, since the district sanitary inspector of the Health Committee, who was instructed to report the unvaccinated he came across, reported over 230 in a few streets, all of whom were duly referred to the vaccination officer. A few of these may have been below the limit at which vaccination is compulsory by law and a few may have been adults, but that, in the face of the grave danger, is no ground for withholding the protection which vaccination affords. Even in some of those cases to which attention was called a somewhat inexplicable delay arose in effecting vaccination, and in two instances the children, after the lapse of thirteen days and seven days respectively after attention had been called to them, were attacked with small-pox and removed to the hospital.

"The class of people who suffer most by small-pox are the lowest and most indifferent of the population. The exhibition of placards upon the street corners is but of small avail in securing the vaccination of people such as these. Many of them probably cannot read. The only effectual course to pursue in order to discover the unvaccinated is the employment of an adequate staff of trained and intelligent people who will be able by persuasive means to secure, not only attention to primary vaccination, but will be able to advise successfully the revaccination at the appropriate age.

"The incidence of small-pox and its confinement to the Toxteth district are remarkable. Out of a total of 236 cases dealt with from Sept. 1st up to Jan. 20th, no less than 192 occurred in the Toxteth district; but the danger was by no means confined to that area, for 11 of the 44 cases which occurred in other parts of the city were proved to be directly infected by intercourse with Toxteth cases, and it is not improbable that they in turn infected others. The outbreak on the *Clarence* was traceable to a similar source."

Dr. Hope proceeds to deal with the question of vaccination, and concludes his report thus: "Relative mortality amongst vaccinated and unvaccinated patients in the Toxteth Park district from Sept. 1st, 1894, to Jan. 20th, 1895: Number of vaccinated patients, 151; died, 8; percentage, 5.3. Number of unvaccinated patients, 41; died, 10; percentage, 24.3."

ROYAL INSTITUTION.—At the general monthly meeting of the Members of the Royal Institution, held on the 4th inst., Sir James Crichton-Browne presiding, the special thanks of the members were returned to Professor Dewar for his donation of the Ramford Prize money to the fund for the promotion of experimental research at low temperatures.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE ordinary quarterly comitia of the College was held on Jan. 31st, Sir J. Russell Reynolds, President, in the chair. At the opening of the proceedings the President reported to the College that Dr. Allchin and he had attended the deputation to the Prime Minister to urge on the Government to take steps towards the appointment of a Statutory Commission, as proposed by the Gresham University Commissioners; and that Dr. Allchin had, at his request, addressed the Prime Minister on behalf of the College.

Drs. T. V. Dickinson, J. Fawcett, L. Humphry, Mr. E. G. Little, Drs. J. P. Parkinson, A. Ransome, Whitley Bland Stokes, S. R. Wells, and L. Wilde were admitted Members of the College.

Licences were granted to 139 candidates who had passed the recent examination, and the diploma in public health (granted conjointly with the Royal College of Surgeons) to thirteen candidates at the examination in that subject.

Communications were received—(1) from the Secretary to the Royal College of Surgeons of England reporting the proceedings of the Council of that body; (2) from Mr. W. H. Baillie, presenting to the College a portrait by Hoppner of Dr. Matthew Baillie, and one of Dr. Edward Jenner by Sir Thomas Lawrence; and (3) from Sir R. Quain, presenting to the College a silver cup for the use of the Fellows' Club.

Thanks were voted to Mr. Baillie and Sir R. Quain for their gifts.

The President presented to the College on behalf of Dr. Theodore Williams a pencil drawing of Dr. Richard Mead by his contemporary, Dr. Stukeley, and in doing so gave some interesting details concerning Drs. Mead and Stukeley.

The thanks of the College were accorded to Dr. C. T. Williams for his gift.

On the motion of the Senior Censor a vote of congratulation to the President on the honours conferred upon him by Her Majesty the Queen was heartily accorded by the Fellows, and acknowledged by Sir Russell Reynolds in appropriate terms.

The following Fellows were, on the nomination of the Council, elected to fill vacancies on the Council—viz., Dr. Hensley, Dr. Gervis, Dr. Ord, and Dr. Cavafy.

It was resolved, on the motion of the President, seconded by Dr. C. T. Williams, that during the annual meeting of the British Medical Association in London in August next a conversazione be given in the College, and that as many members of the Association be invited as space will permit. It was further decided to leave the arrangements in the hands of a committee to be nominated by the President.

The Registrar moved, and the Treasurer seconded, and it was resolved for the first time to make the alterations in By-laws cxlii. and cxlixi. relating to the fees payable by Fellows and Members agreed on by the College at a previous meeting.

The report of the Weber Prize Committee was received, on the motion of Dr. J. E. Pollock, the chairman of that committee. The report enumerated the regulations for the triennial award of a prize of 150 guineas, to be called the Weber-Parkes Prize, "to the writer of the best essay upon some subject connected with the etiology, prevention, pathology, or treatment of Tuberculosis, especially with reference to pulmonary consumption in man," the prize to be accompanied by a bronze medal specially designed, a similar medal being given to the next in order of merit. It further provided for the nomination of an adjudication committee, whose duty it would be to select the subject upon which they will adjudicate. The competition was proposed to be open to the world, and a provision was made for the bestowal of the award for original work produced within the stated period in the event of no essay being sent in of sufficient merit to receive it. The reception of the report having been carried it was further resolved, on the motion of the treasurer, to refer it back to the committee before its final adoption, in order to make some provision for the remuneration of the members of the proposed adjudication committee.

The report of the representative of the College on the General Medical Council (Sir Dyce Duckworth) was read, and a vote of thanks accorded to him for his services.

Reports were also received from the Finance Committee

and from the Committee of Management, and a return of the results of the examinations of the past year from the examiners.

THE MEDICAL DEFENCE UNION, LIMITED.

AN ordinary general meeting of the Medical Defence Union was held at the rooms of the Royal Medical and Chirurgical Society of London on Wednesday last to receive the annual report of the council and the statement of accounts for the past year and to transact other business. The President of the Union, Mr. Victor Horsley, presided.

In moving the adoption of the Report, Mr. Victor Horsley desired to congratulate the Union on having, in spite of various obstacles, passed through the most successful year of its existence. In the first place, as regards membership the increase—namely, 781—is greater by 200 than the increase of any previous year. The Guarantee Fund has during the year increased by nearly £1000, and now amounts to over £5000. During the year every liability has been discharged out of the income and the most rigid economy observed, an economy which the working of the Finance Committee has greatly contributed to. The result is that this year not only have the heavy liabilities of the previous year been cleared off, but a handsome surplus remains. He particularly desired to draw attention to the fact that during 1894, in addition to the charges for the year, a legal account of Messrs. Johnson and Co., presented for work done in 1893 and amounting to over £350, was paid. This does not appear in the balance sheet for 1894 because the liability which was stated in the balance sheet for 1893 had been thus got rid of, the balance sheet of course only stating what liabilities remained on Dec. 31st, 1894. The work of the Union during the past year has been singularly successful. In the first place, as regards the defence of members the existence of the Union of recent years has caused a diminution in the cases of blackmailing, and this year the prompt action of the Union has so crushed the assailants in every case that not in one instance during 1894 was there any necessity for going into court. Much friction has arisen with public bodies in regard to the Infectious Disease (Notification) Act, and actions for damages have been made against members of the profession arising out of their certificates. The Union has won every case of this kind. As regards the prosecution of unqualified persons, for the first time a bonesetter has, in an action by the Union, been successfully prosecuted, and in all the other prosecutions of quacks by the Union penalties have been inflicted and costs recovered. The development of the Union has been so rapid and the increase in its work so great that it has been found necessary to revise the articles of association, and a committee is now sitting and has already agreed upon certain fundamental principles of revision. A plan, which it is hoped will receive both the support of the Union and the British Medical Association, has been suggested whereby the Defence Union should be in a measure affiliated to the Association, and, without losing its present successful independent power of working for the defence of its members, it should also operate as a department of the Association. For this purpose it is proposed that the Association should grant a subsidy to the Medical Defence Union of a considerable sum—say of £1000 or £1500 a year—under the condition that it is to be expended in the prosecution of quacks. Further, that to properly provide for the administration of the same a certain number of members (say six) of the Council of the Association should be placed on the council of the Union, and that the latter should be known as the British Medical Defence Union. This plan seemed to him to be extremely practical, because, although the Medical Defence Union has all the experience and machinery for the prosecution of unqualified persons and although it has ample funds for the defence of its individual members, it naturally has not means sufficient to deal with the evil of quackery as completely as could be wished.

Dr. Bridgwater, in seconding the motion, congratulated the members of the Union on the admirable report which had been presented. He was glad to see that the name of the Union was becoming a power in the country, and it was gratifying to know that they might now consider themselves as a "good going concern." A good deal of their financial success was due to the honest method of "paying

your debts as they are contracted," and he thought that members who had not paid up their subscriptions might take the hint from this that their funds were needed.

The report was carried.

The following retiring members of the council—Dr. Danford Thomas (London), Mr. Hall-Wright (Birmingham), and Mr. Horder (Cardiff)—were re-elected.

In reply to a member, Mr. Horsley said that he quite agreed that there should be one paid secretary only, who should attend solely to the business of the Union. The matter was under consideration.

The usual courtesies to the chairman were tendered by Dr. Jones, who was cordially supported by the meeting.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6366 births and 4000 deaths were registered during the week ending Feb. 2nd. The annual rate of mortality in these towns, which had been 21·7 and 18·7 per 1000 in the preceding two weeks, rose again last week to 19·7. In London the rate was 19·0 per 1000, while it averaged 20·2 in the thirty-two provincial towns. The lowest rates in these towns were 11·8 in Croydon, 14·6 in Portsmouth, 16·0 in Birmingham, 16·3 in West Ham, and 16·8 in Huddersfield; the highest rates were 23·5 in Manchester, 24·4 in Brighton, 25·3 in Salford, 26·8 in Preston, and 27·9 in Liverpool. The 4000 deaths included 299 which were referred to the principal zymotic diseases, against 338 and 328 in the preceding two weeks; of these, 76 resulted from whooping-cough, 70 from diphtheria, 48 from measles, 45 from diarrhoea, 33 from "fever" (principally enteric), 25 from scarlet fever, and 2 from small-pox. No fatal case of any of these diseases occurred last week in Leicester or in Halifax; in the other towns they caused the lowest death-rates in Cardiff, Bristol, and Bradford, and the highest rates in Brighton, Preston, Wolverhampton, Bolton, and Salford. The greatest mortality from measles occurred in Bolton, Preston, and Gateshead; from scarlet fever in Salford; and from whooping-cough in Brighton, Plymouth, Salford, Huddersfield, and Swansea. The 70 deaths from diphtheria included 45 in London, 3 in Birmingham, 3 in Manchester, and 3 in Blackburn. Two fatal cases of small-pox were registered in London, but not one in any other of the thirty-three towns. There were 51 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highbury Small-pox Hospital on Saturday last, the 2nd inst., against numbers increasing from 15 to 35 at the end of the preceding six weeks; 21 new cases were admitted during the week, against 8, 6, and 8 in the preceding three weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1653, against 1713, 1653, and 1652 on the three preceding Saturdays; 160 new cases were admitted during the week, against 130, 154, and 186 in the preceding three weeks. The deaths referred to diseases of the respiratory organs in London, which had been 399 and 324 in the preceding two weeks, rose again to 377 last week, but were 126 below the corrected average. The causes of 77, or 1·9 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Leeds, Newcastle-upon-Tyne, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Preston, Halifax, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 28·3 and 24·2 per 1000 in the preceding two weeks, further declined to 23·9 during the week ending Feb. 2nd, but was 4·2 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·5 in Leith and 15·3 in Paisley to 25·7 in Perth and 26·5 in Glasgow. The 690 deaths in these towns included 37 which were referred to measles, 25 to whooping-cough, 12 to scarlet fever, 6 to diarrhoea, 6 to "fever," 3 to diphtheria, and not one to small-

pox. In all, 89 deaths resulted from these principal zymotic diseases, against 100 and 92 in the preceding two weeks. These 89 deaths were equal to an annual rate of 3·1 per 1000, which was 1·6 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had declined from 58 to 42 in the preceding three weeks, further fell to 37 last week, of which 15 occurred in Glasgow, 10 in Edinburgh, and 9 in Aberdeen. The 25 deaths from whooping-cough exceeded by 7 the number in the preceding week, and included 21 in Glasgow. The fatal cases of scarlet fever, which had increased from 6 to 9 in the preceding three weeks, further rose to 12 last week, of which 7 occurred in Glasgow, 2 in Edinburgh, and 2 in Paisley. The deaths referred to different forms of "fever," which had been 5 in each of the preceding two weeks, were 6 last week, and included 3 in Glasgow. The 3 fatal cases of diphtheria showed a further decline from the numbers recorded in recent weeks, and included 2 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 235 and 186 in the preceding two weeks, further declined to 168 last week, but exceeded by 40 the number in the corresponding period of last year. The causes of 54, or nearly 8 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 40·9 and 31·0 per 1000 in the preceding two weeks, rose again to 31·9 during the week ending Feb. 2nd. During the past five weeks of the current quarter the death-rate in the city has averaged 32·6 per 1000, against 18·7 in London and 23·7 in Edinburgh. The 214 deaths registered in Dublin during the week under notice showed an increase of 6 upon the number in the preceding week, and included 16 which were referred to the principal zymotic diseases, against 23 and 20 in the preceding two weeks; of these, 5 resulted from small-pox, 4 from "fever" (principally enteric), 3 from whooping-cough, 3 from diarrhoea, 1 from scarlet fever, and not one either from measles or diphtheria. These 16 deaths were equal to an annual rate of 2·4 per 1000, the zymotic death-rate during the same period being 1·4 in London and 2·5 in Edinburgh. The fatal cases of small-pox, which had been 11, 10, and 7 in the preceding three weeks, further declined to 5 last week. The deaths referred to different forms of "fever," which had increased from 2 to 5 in the preceding four weeks, were 4 last week. The mortality from whooping-cough showed a slight increase upon that recorded in the preceding week, while that from scarlet fever showed a decline. The 214 deaths in Dublin last week included 31 of infants under one year of age and 59 of persons aged upwards of sixty years; the deaths of infants showed a slight increase, while those of elderly persons showed a further decline from recent weekly numbers. Five inquest cases and 7 deaths from violence were registered; and 84, or more than a third, of the deaths occurred in public institutions. The causes of 15, or 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-CAPTAINS Baylor and Riordan have embarked in the *Jumna* for duty in Malta, and the following officers have embarked in the *Britannia* for a tour of service in India:—Surgeon-Lieutenant-Colonel Saunders, Surgeon-Captain Kelly, and Surgeon-Lieutenants Bray, Hinge, and Erskine. Surgeon-Major Clements has embarked for service in Sierra Leone. The following Surgeons on probation, who have just passed out of Netley, have proceeded to Aldershot to undergo a course of instruction at the depot, Medical Staff Corps: W. S. Harrison, H. Howell, D. Lawson, E. Steel, C. Profeit, F. Kiddle, H. Staddon, J. Whitehead, J. Morison, L. Tomlinson, S. J. Perry, and A. Heaton.

ARMY MEDICAL STAFF.

Surgeon-Lieutenant-Colonel Barnard William Wellings retires on retired pay.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Lieutenants E. W. Slayter and T. P. Jones have

on arrival from England been posted to general duty, Poona district. Surgeon-Captain J. L. T. Jones and Herbert Herbert have respectively delivered over and received charge of the Kaira Prison. Surgeon-Major R. W. S. Lyons, M.D., has delivered over the charge of the Ratnagiri Prison. Brigade-Surgeon-Lieutenant-Colonel J. C. G. Carmichael, M.D., I.M.S., Officiating Principal Medical Officer, Presidency district, and Surgeon-Major A. V. Lane, A.M.S., Aden, have been granted leave to England. Surgeon-Lieutenant J. A. Howell, I.M.S., Civil Surgeon, Karwar, retires from the service.

NAVAL MEDICAL SERVICE.

Staff-Surgeon Otway Peter Browne, B.A., M.B., has been placed on the Retired List of his rank.

VOLUNTEER CORPS.

Rifle: 2nd Volunteer Battalion, the Northumberland Fusiliers: Surgeon-Major A. Wilson to be Surgeon-Lieutenant-Colonel. 2nd Volunteer Battalion, the Princess of Wales's Own (Yorkshire Regiment): Surgeon-Major W. T. Colby, M.D., to be Surgeon-Lieutenant-Colonel. 4th (Donside Highland) Volunteer Battalion, the Gordon Highlanders: Samuel George Davidson, M.B., to be Surgeon-Lieutenant.

THE WAR BETWEEN CHINA AND JAPAN.

Colonel Maurice, in an article on this subject (to which we briefly alluded last week) in the last number of the *United Service Magazine*, warns us that with some half a million of men round Peking whose habits are filthy and who are without discipline or organisation, or any regard for ordinary sanitary precautions, pestilence in some form or other is likely to follow on the accession of warm weather, when the melting of the snow, befouled by vast numbers of men and animals, takes place, and he asks how soon afterwards actual sickness may be expected to appear. It is, of course, quite probable that some outbreak of epidemic disease may occur under the circumstances and conditions he depicts, but its exact nature must be a matter of conjecture in the meantime. The conditions described may be said to represent a manufactory for disease of some sort, or rather they present a fitting soil for the rapid growth and development of any disease-cause that may be present or introduced. With a recent history of plague in China and Hong-Kong the liability to epidemic cholera, or to outbreaks of typhoid fever or other diseases, it is not easy to say what, may arise; and we cannot determine the interval that will ensue before a disease becomes widespread and epidemic unless we know the particular form of sickness with which we have to deal. But assuming that it is one capable of being spread by water, from about ten to thirty days would elapse in the case of typhoid fever, for example, whereas the interval would probably be much less than the first-named period in the case of cholera. As regards typhoid fever, there is a very instructive epidemic on record in connexion with Plymouth, Pennsylvania, a town of 8000 inhabitants. The dejects of a typhoid fever patient were, during part of the first three months of the year 1885, thrown out on the snow, under which the ground of a hill sloping towards the water-supply of the town was deeply frozen. On March 25th a sudden and great thaw occurred, and the water did not sink into the ground, but immediately ran off into the natural surface channels. On April 10th the epidemic began, which affected 1200 persons and caused 130 deaths. This may be said to approximately represent the conditions described by Colonel Maurice. The medical history of our last war in South Africa will also furnish some interesting data of a somewhat similar character *apropos* of wholesale water contamination.

THE NEW TROOP SERVICE SYSTEM.

Army medical officers who have made voyages to India in Her Majesty's troopers will be interested in knowing what is thought of the steamers employed under the present system. According to an apparently well-informed correspondent writing to a service contemporary the new system of transport seems to have advantages and disadvantages as compared with that of the old service of Her Majesty's Indian troopship which it has replaced. The passage to India is several days quicker, and the accommodation for officers and ladies, warrant officers, and married non-commissioned officers is much better in the present vessels, but the men are no better off, indeed, rather worse off, than they were, mainly owing, it is alleged, to the insufficient space afforded on the upper deck

and on the troop decks. This renders the proper inspection of the troops and the maintenance of ventilation and cleanliness difficult.

THE LATE PLAGUE AT HONG-KONG AND THE SHROPSHIRE REGIMENT.

Although the Shropshire Light Infantry received great credit locally for the work they performed in Hong-Kong nine months ago, in connexion with the outbreak of plague at that station, we doubt whether their conduct on that occasion obtained all the credit it deserved elsewhere. The visitation was a severe one, and gave rise to a great panic and exodus among the native population, the name of the disease alone being sufficient to create great alarm. The officers and men of the regiment came forward in a very brave and unselfish manner, and constituted themselves into a sanitary service which did a lot of practical work of an essential kind with highly successful results. Members of the medical profession are best qualified perhaps to gauge the merit of labours of this sort.

THE COMPETITIVE EXAMINATION FOR THE ARMY MEDICAL STAFF.

We would call attention to the fact that the next examination of candidates for twelve commissions in Her Majesty's Army Medical Staff is to be held at the Examination Hall, Victoria Embankment, on the 15th inst. and following days.

THE NEW DRAINAGE WORKS AT ALDERSHOT.

The *Army and Navy Gazette* states that the War Office, after consultation with the local civil authorities, has obtained the sanction of the Treasury for a vote of £60,000 for the purpose of expediting the new drainage works at Aldershot. Let us hope that we may now hear of a new site being chosen for, and an altogether better sewage farm being provided for the camp than that now in use, which is universally recognised as unfit and unsuitable for the purpose. There have recently been some cases of typhoid fever among the officers stationed at Aldershot, the origin of which was variously attributed to defective barrack drainage or the nuisance caused by the sewage farm, but it is rumoured that some samples of drinking water have not afforded satisfactory results on analysis and examination. The health of the troops generally is, however, as far as we can at present learn, good.

An order that deserves a word of commendation has been issued by the General Officer commanding at Lucknow. Some of the British soldiers having dressed in khaki during the early morning, the attention of the officers in charge has been drawn to the necessity of soldiers being properly clothed. Khaki is only to be allowed between 9 A.M. and 5 P.M. unless otherwise ordered.

The appointment of Principal Medical Officer of all India, which post is about to be vacated by Surgeon-Major-General Bradshaw, will be conferred upon Surgeon-Colonel Gore, now serving in Bombay.

H.M.S. *Malabar* is expected to arrive at Portsmouth about Feb. 9th with nine patients for Netley.

We hear that a sum of £25,000 is to be expended on repairs at the Royal Victoria Hospital, Netley.

LITERARY INTELLIGENCE.—"The Royal Natural History," which we have perused from the beginning of its issue with the greatest interest and respect for the enterprise of those in charge of the production, having completed the series of its numbers devoted to the world's "Mammals," begins in this month's issue an interesting and well-illustrated account of the "Birds," past and present. Among the contributors are the editor—Mr. Lydekker, F.R.S.—Dr. Bowdler Sharpe, Mr. Macpherson and Mr. Ogilvie Grant, and among the illustrators are Keulemans, Smit, Lodge, Specht, and Gambier Bolton. Messrs. Frederick Warne and Co., the publishers, announce that the nine parts, which comprise the above, will contain over 400 illustrations.—A new *Elementary Text-book of Anatomy*, by Mr. Henry E. Clark, editor of Wilson's "Student's Vade-Mecum," will very shortly be published by Messrs. Blackie and Son, Limited, Glasgow.—Messrs. Selwin Tait and Sons of New York have issued an edition of Dr. Norman Kerr's "Inebriety" for the United States.

Correspondence.

"Audi alteram partem."

DEFECTS OF VISION IN THE MERCANTILE MARINE AND RAILWAY SERVICES.

To the Editors of THE LANCET.

SIRS,—In this seafaring community the published statements have made a profound impression that such shocking accidents as that of the *Elbe*, with its appalling loss of life, can be traceable to the defective eyesight of mercantile marine officers and sailors on shipboard as the probable cause of many such disasters, and "quite possibly," in the opinion of to-day's *Times*, "the actual cause in the case of the *Elbe*." So the public has good ground for asking the pertinent question, Why has not the Board of Trade kept pace with science, and revised their medical regulations? Why is the eyesight of the shipmaster tested for the last time upon obtaining the certificate of that rank instead of continuous re-examinations at intervals rendered necessary by age deterioration, bearing in mind that his previous examinations were incomplete on points of vital, practical importance in the commander of a passenger ship? For the correct reply to these questions we must go to the root of the evil. It is an open secret that the Marine Department of the Board of Trade has no medical adviser, no professional head analogous to the Director-General of the Medical Departments of the Army and of the Royal Navy. The medical surveyors, who are also the medical inspectors of emigration at our ports, and the unorganised crowd of ship surgeons, all should be in touch with the Board of Trade through such a head of a health department of the most important mercantile marine in the world. Until this appointment is made there will be no security that the forthcoming revised regulations *re* vision tests will not share the fate of other sanitary requirements of the Board of Trade, and be either evaded or carried out perfunctorily, as illustrated in my paper upon the Medical Department of the Mercantile Marine, published in the recent volume of the Transactions of the Sanitary Institute (Congress at Liverpool, 1894).

I am, Sirs, yours faithfully,

C. H. LEET, F.R.C.S.

Norma-road, Waterloo, Liverpool, Feb. 2nd, 1895.

To the Editors of THE LANCET.

SIRS,—On reading the account of the deputation of medical men who waited upon Mr. Bryce at the offices of the Board of Trade yesterday afternoon in connexion with the eyesight of seamen and railway servants I notice that the latter gentleman is reported to have said that "the department had always shown due vigilance in the matter of the eyesight of seamen." In order to show that this vigilance is, to say the least, not sufficient, I shall mention the case of a man who called upon me professionally, but not on account of his eyes, on Dec. 18th, 1891. Observing that he had marked external strabismus of the left eye, I proceeded to examine the state of his vision, which was as follows:—R.V., $\frac{1}{4}$ (one letter wrong); no improvement by lenses. L.V., $\frac{1}{8}$; no improvement by lenses. The right cornea had a fair-sized nebula. The left cornea was obscured by numerous opacities. In other words, this man had less than one half the normal vision in his right eye, and only $\frac{1}{8}$ th part in his left, with the probability of still further deterioration. This man was an able seaman, employed up to the time of my accidental examination on board a steamship conveying passengers to keep watch on deck, by night or by day, during its frequent journeys between ports on the North Sea. I considered it my duty to inform the officials of the company to which the ship belonged that my patient was unfit for such "look-out" work, and I had a letter of thanks telling me that more suitable employment had been provided for him.

Doubtless this company has taken precautions against a similar case occurring in future; but the Board of Trade and all shipping and railway companies should know that a medical man is the only suitable person for examining eyesight. He is the only person who could diagnose and treat cases of tobacco blindness, which to a certainty occur frequently in the mercantile marine. This and other diseases may seriously affect the vision at any time, and on this account an initial examination is quite insufficient. Periodical

examinations should be made in the case of all responsible persons. In replying to the deputation, Mr. Bryce said it was a remarkable fact that few accidents had been traced to defective eyesight, either at land or sea. It is a remarkable fact, but one which gives additional significance to the belief that many accidents, both explained and unexplained, may have been due to defective eyesight. I am not aware of a single case where serious catastrophe has occurred in which the question of the eyesight of those charged with the "look-out" was either inquired into or an inquiry even suggested. Until the eyesight of all responsible persons is systematically and periodically examined by medical men it is entirely misleading to say that few accidents are caused by defective eyesight because few have been traced to that cause.

I am, Sirs, yours faithfully,

A. RUDOLF GALLOWAY, M.B., C.M., M.A.

Union-street, Aberdeen, Feb. 2nd, 1895.

"THE ABSENCE OF SUGAR FROM NORMAL URINE PROVED BY A NEW AND SIMPLE METHOD."

To the Editors of THE LANCET.

SIRS,—Sir George Johnson still persists. He must not therefore complain if I subject his letter, which appeared in THE LANCET of Jan. 26th, to the sharp criticism to which it is open.

Sir George Johnson remarks: "No physician, probably, has larger experience of the fermentation test than Sir William Roberts, who says, 'According to my experience urine containing 0.5 per cent., or two and a half grains to the ounce and under, yields no sign to the fermentation test.'" What are we to understand from this quotation, made use of without any qualification? It is quite meaningless if not intended to be associated with the implication that upon Sir William Roberts' authority the fermentation test will not reveal the presence of sugar in urine when existing below 0.5 per cent. As normal urine is only affirmed to contain much less than this, *ergo*, upon Sir William Roberts' dictum, put as Sir George Johnson has put it, normal urine cannot be shown by the fermentation test to contain sugar. Sir George Johnson omits to mention that what Sir William Roberts says refers distinctly to the application of the fermentation test in a direct manner to diabetic urine, whilst, as everyone knows, when used in connexion with normal urine it is applied to the extracted sugar. Sir George Johnson has here placed himself in this dilemma: either his perceptive power has been insufficient to enable him to properly grasp the situation, or, in his endeavour to score a point in argument, he has considered himself at liberty to neglect to give consideration to the misleading effects of putting an incomplete representation before your readers.

Next follows: "Dr. Pavy states that he got a negative result with this test [fermentation] applied to normal urine until he was led to neutralise the acid urine [in reality, I say nothing about the acid urine; I distinctly speak of the acid product from the urine] by carbonate of soda; he then found fermentation proceeded actively. Now, one effect of adding carbonate of soda to acid urine would be to set free carbonic acid, and it would be interesting to know whether Dr. Pavy was careful to ascertain that the carbonic acid which was given off from the urine at a 'suitable temperature' was not that which had been previously combined with the sodium." I take it Sir George Johnson cannot mean what he writes as intended to be read in earnest. He must be indulging in some kind of jest which does not show itself upon the surface. The suggestion borders too much upon the absurd to conceive that it should be otherwise. If, however, anything should be possibly considered to be further wanted, I may state that if Sir George Johnson had turned to the reference given in my book from which he has quoted, he would have found that in the application of the test not only was the evolution of carbonic acid by unmistakable fermentation observed, but also the chemical recognition of the production of alcohol.

Then, as to the phenyl-hydrazine test, Sir George Johnson says: "Dr. Pavy assumes that the formation of osazone crystals affords conclusive evidence of sugar being present; but Dr. Noel Paton, in the paper above quoted [a paper contained in the December number of the *Edinburgh Medical*]

Journal on the Physiology of the Carbo-hydrates, which, I may announce by the way, will be shortly criticised by me], says: "The carbohydrates are not the only bodies which yield crystalline compounds with phenyl-hydrazine. A glance at Beilstein's 'Organic Chemistry' shows that a vast number of substances give such crystalline compounds." There is nothing new in being told that there are other substances besides sugars that yield crystalline osazones with phenyl-hydrazine. The bodies that do so, however, are restricted to those which, by virtue of their molecular constitution, belong to the aldehydic and ketonic groups. It is not the mere fact of the formation of a crystalline osazone that is relied upon, but the distinctive characters presented as regards form, melting point, and solubility.

Sir George Johnson seems to consider it no offence to literary proflity to quote from an author as far as he finds it convenient and to stop short when he comes to that which does not suit his purpose. In this particular instance, the very thing which he is striving to deny is given as a proven point, brought to bear in connexion with another matter, by his author in the succeeding words to those abstracted for use! Running on from the quotation given above by Sir George Johnson Dr. Paton says: "It is only when an elementary analysis of the compound [osazone] is made that it can be definitely concluded that a carbohydrate is a constituent part. Such analyses are given by Baisch in his researches on the carbohydrates of the urine, and by Bial in his observations on the sugar produced by the ferment of the blood, and the conclusions of these authors are thus placed beyond doubt." (The italics are mine.)

Passing to Von Baisch's own writing, the effect of what he says¹ is that the existence of sugar in normal urine is susceptible of demonstration by the polarimeter, evidenced by crystalline from melting-point and composition, by Fehling's solution, by the production of glucosazone with phenyl-hydrazine, and by fermentation with yeast with the formation of alcohol.—I am, Sirs, yours faithfully,

Grosvenor-street, Jan. 30th, 1895.

F. W. PAVY.

* * Dr. Pavy's letter was received last week, but did not reach us till too late for insertion.—ED. L.

To the Editors of THE LANCET.

SIRS,—If Mr. Allen had carefully read the paper which he has done me the honour to criticise he surely would not have made the numerous inaccurate statements to which he has committed himself. With your permission I will briefly reply to some of his assertions which call for special notice. In the early part of his letter he incorrectly states that I do not claim for the picric acid reaction that it is "absolutely reliable" as applied to urine containing less than 2 grains of sugar per ounce. Yet in a subsequent paragraph he truly states that I place the limit of delicacy at 0.01 per cent., this being one-fifth the amount which Dr. Pavy in his book and Mr. Allen in a previous communication to THE LANCET² declare to be present in normal urine. How does Mr. Allen reconcile these conflicting statements?

Again, Mr. Allen politely suggests from the concluding paragraph of my paper that I am ignorant of the fact that an ounce of water weighs 437.5 grains, not 480 grains. The following is the paragraph referred to: "The percentage weight of sugar to the volume of urine may be ascertained by dividing the number of grains per fluid ounce by 4.8." My critic would doubtless resent the suggestion that he is ignorant of the fact that a fluid ounce contains 480 minims, and therefore that in urine containing 4.8 grains per fluid ounce the proportion of weight to volume is 1 per cent. There is here no question as to the weight of distilled water. In our English system there is not the direct relation between the volume and weight of water as in the foreign metrical system. Thus, 1 c.c. of water weighs 1 gramme, while 1 minim weighs 0.911 grain. It is, therefore, simpler, if not more correct, to speak of the percentage of grains to the volume of the liquid analysed rather than to the weight of water. Mr. Allen erroneously attributes to me the view that any amount of sugar less than 2 grains to the ounce may be safely neglected, and this notwithstanding my repeated assertion that as normal urine contains neither sugar nor albumen the smallest trace of either is pathological, and therefore may not be "safely neglected."

Mr. Allen's statement that it is impossible to distinguish slight differences of tint in liquids, that the colour resulting from the picric acid reaction is "blood-red," "brown-red," and even "deep coffee brown," indicates either that he has had scarcely any experience of the test or that he has the misfortune to be colour-blind. The dark-red colour which results from testing a liquid which contains more than 1 grain of sugar per ounce is by dilution brought to the ferric acetate standard colour, which is neither blood-red nor brown-red. It is practically easier to ascertain the identical shade of two bright red liquids placed side by side than to determine the exact point at which the blue colour finally disappears from Dr. Pavy's valuable ammonio-cupric solution. Mr. Allen's *a priori* assumption that there is no strict relation between the degree of picramic acid colour and the amount of sugar in solution is disproved by numerous conclusive observations and experiments. When a known weight of glucose, varying from a small fraction of a grain to 40 grains per ounce or more, is dissolved in water the amount is indicated with the greatest facility and certainty by the colour test. When the amount of sugar is less than half a grain to the ounce the quantitative determination is made by diluting the standard solution in an accurately graduated tube until the colour of the weak saccharine solution is equalled.

Mr. Allen says that I must have been exceptionally fortunate in obtaining picric acid which does not give a red colour "when boiled with caustic alkali." If by caustic alkali Mr. Allen means solid caustic potash or a strong solution of the same, he surely must know that by this violent agent a solution of the purest picric acid is decomposed and reddened; but the liquid used for sugar testing is the weak liquor potassæ (P.B.), and using this solution I have, during many years' experience of picric acid, met with only one specimen which gave a red colour when boiled with potash, and that was a manifestly impure specimen.

This impure specimen not only gave a red colour with liquor potassæ but the boiled liquid was turbid. When a saturated aqueous solution of pure picric acid is boiled with half its volume of liquor potassæ (P.B.) the result is a pale yellow transparent liquid, without the slightest tinge of red, which on cooling deposits the pale yellow picrate of potash. Whether, as Mr. Allen suggests, "caustic potash is apt to contain traces of cyanides which react with picric acid exactly like sugar" I do not know; but this I do know, that no specimen of liquor potassæ that I have met with has produced this reaction with pure picric acid. My friendly critic may rest assured that I am careful to ascertain the purity of both the picric acid and the potash which I employ as test agents.

Mr. Allen, acting as *advocatus Diaboli*, having cleared the way by exposing the imaginary vices of picric acid, goes on to proclaim the supposed virtues of M. Crismer's "safranine" test. As this is admitted not to be a quantitative test its advantages are not so obvious as its advocate declares them to be.—I am, Sirs, yours faithfully,

Savile-row, W., Feb. 4th, 1895.

GEORGE JOHNSON.

To the Editors of THE LANCET.

SIRS,—The fact that Dr. Pavy has obtained from normal urine a substance which undergoes the alcoholic fermentation with yeast is the strongest argument he has adduced that the substance in question is sugar. I find, however, on referring to p. 181 of his book, that the material he operated with was "strongly acid" and did not ferment with yeast till rendered alkaline with sodium carbonate. Sir George Johnson, in his letter published in THE LANCET of Jan. 26th, points out that here is a serious source of error, for the carbonic acid obtained might possibly originate by the interaction of acid and sodium carbonate. Acting on this suggestion, I have performed a few experiments which may not be uninteresting to those who have followed with attention the discussion between Sir George Johnson and Dr. Pavy. I took some yeast and found by control experiments that it caused the usual fermentation with a solution of dextrose. Next I found that the same yeast caused fermentation in some normal urine to which 1 per cent. of dextrose had been added; the acidity of the urine did not, therefore, inhibit the activity of the yeast. With normal acid urine, without any addition of sugar, it caused no fermentation, and with the same urine rendered faintly alkaline by ammonia the result was also negative. But in a third specimen, in which neutralisation had been effected by sodium carbonate, there

¹ Zeitschrift für Physiologische Chemie, Band xviii., p. 193.

² THE LANCET, July 28th, 1894.

was an abundant evolution of carbonic acid gas. To a fourth specimen sodium carbonate was added, but no yeast; no gas was formed, showing that the salts to which urine owes its acidity do not of themselves decompose sodium carbonate. All these tubes were inverted over mercury and kept at a suitable temperature for the action of the ferment. One other tube was added to the list; this contained a dilute solution of sodium carbonate and yeast, no urine being added. Here also there was a formation of the gas. These experiments show that in testing for sugar by the fermentation test the use of sodium carbonate is inadmissible; and if it is found necessary to correct the acidity of a suspected sugar some other alkaline substance must be employed. The ammonia used in the experiment just recorded was not sufficiently strong to kill the yeast, as control experiments showed it to be still active after being exposed twenty-four hours in the faintly ammoniacal urine.

I am not prepared to explain how it is that carbonic acid gas forms on adding yeast to sodium carbonate. Two explanations suggest themselves: one is that the yeast has the power of decomposing that salt; the other is that the yeast itself contained some sugar which was decomposed by the cells in a medium containing sodium carbonate. For the present I am rather inclined to adopt the former hypothesis; for in the specimen of weakly ammoniacal urine there was no formation of gas, and, moreover, I have not succeeded in discovering alcohol in the tubes containing sodium carbonate with or without urine after being exposed to the action of the yeast. I may add that the yeast I used was slightly acid—this might be a possible explanation for its action.

With regard to the general question whether or not normal urine contains sugar I think that a careful study of the researches of Seegen and of Baesch, in which more stringent chemical methods were used than those employed by Dr. Pavy, will convince the impartial observer that a small quantity of glucose is obtainable. Whether this is artificially produced by the method of analysis, as suggested by Sir George Johnson, is a subject that demands renewed research. Dr. Pavy gives the percentage of sugar in normal urine about five times greater than has been found by these observers, and I think his high figure is most easily explicable by Sir George Johnson's hypothesis—namely, a neglect to take into consideration the reducing action of kreatinine.

I am, Sirs, faithfully yours,

King's College, London,
Feb. 5th, 1895.

W. D. HALLIBURTON.

"THE DEBATE ON THE NATURE AND TREATMENT OF PERITONITIS AT THE OBSTETRICAL SOCIETY."

To the Editors of THE LANCET.

SIRS,—I agree with Dr. Herman that it is a waste of time to discuss whether micro-organisms cause peritonitis—that is, so long as Dr. Herman assumes that they cause all peritonitis. That they do cause some peritonitis I have proclaimed on the hustings. But the jump from some to all is what I will not make. I claim much more for the purgative treatment than the simple relief of distension. I claim that it prevents death after abdominal section of all kinds, and I think it an absolute waste of time to discuss the words we are to use in defining the stages of the fatal process thus prevented. I am satisfied with the facts and most willingly leave the conundra to those who like them.

I am, Sirs, yours obediently,

Birmingham, Feb. 1st, 1895.

LAWSON TAIT.

To the Editors of THE LANCET.

SIRS,—In his letter to you, dated Jan. 26th, Mr. Lawson Tait says, referring to myself: "I agree to admit his conclusion that the cases that die are peritonitis, because we make post-mortems of them and find it so." I have no desire to comment upon Mr. Tait's grammar, but if I understand his meaning I think it necessary to say that I have come to no such conclusion. I have pointed out that there are certain cases of abdominal section which exhibit signs of peritonitis after death, but in which if the abdomen is reopened some days after the operation, when the symptoms which Mr. Tait used to attribute to peritonitis are well advanced, but of course before the patient is moribund, no sign of peritonitis is found. Peritonitis, I hold, is therefore a secondary result in these

cases, and is not the cause of the conditions which lead to the death of the patients. I have asked Mr. Tait, and I ask him again, to explain two contradictory statements made by him: The first, in 1886: "On the slightest indication of peritonitis after an ovariectomy we give a rapidly active purgative, it matters not what; the patient's bowels are moved, and the peritonitis disappears."¹ The second, in 1892: "I have never said that the purgative treatment will cure peritonitis."² Mr. Tait has repeatedly asserted that he has been misrepresented in this matter. I cannot answer for others, but I am not aware that I have ever misrepresented him. He now wishes me to leave him alone. I am willing to do so, but towards this end I would suggest that it would be well for Mr. Tait either to leave this subject alone or to explain what appears to be an inconsistency on his part, and that if he desires to make any further complaint of being misrepresented he should be good enough to state who has misrepresented him, and where the misrepresentation is to be found.

I am, Sirs, your obedient servant,

Portman-street, Feb. 5th, 1895.

JOHN D. MALCOLM.

To the Editors of THE LANCET.

SIRS,—As a general practitioner with a large midwifery practice I for one am grateful to Mr. Lawson Tait for having some time ago published the results of his treatment of peritonitis by purgatives. I am not going to quibble as to the correct terms to be used, but I will say that cases occurred in my practice the symptoms of which were identical with those I am able to recognise in so-called cases of peritonitis, and by the treatment of the old-fashioned plan of rest and opium five out of every six died, but since I have adopted the purgative treatment (mist. alb.) in similar cases I have not had one death. To be able to save the patient's life is to me of far more importance than discussing whether we cure or prevent peritonitis. I am, Sirs, yours obediently,

RICHARD EMMETT.

Woodville, Kingston-road, Portsmouth, Feb. 4th, 1895.

"THE LONDON MEDICAL STUDENTS AND THE UNIVERSITY OF LONDON: A GRIEVANCE."

To the Editors of THE LANCET.

SIRS,—I am a London "Conjoint" man, and I have often felt the disadvantage under which we labour, many times having been told that I was not so highly qualified as Dr. So-and-so, who happened to be the fortunate possessor of a Scotch or provincial M.D. No amount of explanation will disabuse the minds of the laity on this point. My case is that of many. I am emboldened by Dr. Sisley's letter to suggest a remedy. Let Durham be persuaded to grant her M.D. degree (without residence) to practitioners of seven years' standing and not less than thirty years of age, instead of, as at present, to men not less than forty and of fifteen years' standing. After fifteen years in practice few men have either the time, opportunity, or inclination to devote themselves to reading for an examination, but during the first six years or so the case is just the opposite. Were this suggestion acted on much of the disadvantage under which we labour would be done away with.

I am, Sirs, yours faithfully,

Oriel House, Leigh, Essex, Feb. 4th, 1895. STANLEY KIRTON.

To the Editors of THE LANCET.

SIRS,—I have read Dr. Sisley's letter in your last issue, also in the *Standard*, and cannot but wonder why the London diploma should have so many apologies put forth on his behalf. "Qui s'excuse, s'accuse," and it is regrettable that Dr. Sisley's repeated excuses will not tend to raise the conjoint diploma in one's estimation. It is hardly possible that anyone at all conversant with the question would have an opinion otherwise than that a teaching university in London is very desirable; but what most men seem to desire is a degree-mongering institute—a university which will grant a degree to men who have attained to nothing more either in general or professional education than the standard exacted by the London Conjoint Board. The curriculum required for this diploma would not be recognised by any Scotch

¹ Brit. Med. Jour., 1886, vol. i., p. 921.

² Ibid., 1892, vol. ii., p. 1060.

university as sufficient to qualify a man to present himself for the M.B. examination, nor is the preliminary examination deemed sufficient, while the University of Edinburgh does not even recognise such examination. Moreover, the standard in general education required for the M.B. examination is not of itself sufficient for the M.D. degree, and at Edinburgh University the number who graduate to M.D. is only one in four. Dr. Sisley displays a want of knowledge of university regulations and etiquette when he states that a graduate is a "Dr.," while the diplomate is only "Mr." Nobody is entitled to the address of "Dr." by courtesy or otherwise until he has graduated to a doctor's degree in one of the faculties of a university. Bachelors in all faculties are on the same footing in this respect, but the man who is most ready to assume the address of "Dr." is the one with the most inferior diplomas. By all means let us have a teaching university in London, but let it be one which will leave intact the standard of education exacted by the presently existing universities.—I am, Sirs, yours truly,

H. CRITCHLEY, M.A. Durh., M.D. Edin.

London, Feb. 4th, 1895.

"AN ATYPICAL ALBINO."

To the Editors of THE LANCET.

SIRS,—So far from nystagmus being an exceptional phenomenon in albinism, as one might infer from Dr. Squire's report of a case in the last issue of THE LANCET, it is, on the contrary, a very usual accompaniment of that condition. The pigmentless condition of the choroid so frequently met with in albinos, and the defective vision consequent thereon, is generally considered to be the cause of this symptom. To my mind, the interest of Dr. Squire's case rests upon the condition of the choroid, and on this point he has not enlightened us; but since he tells us that there seems to be no inconvenience in the presence of a strong light, and no defect of vision (although with regard to the latter I gather we have only the patient's word to guide us), the inference is that the choroid cannot be very defective. To what, then, is the nystagmus due? In albinism there is generally a total absence of pigment in the irides, but in blue eyes this is not so, but merely a deficiency, a fact which perhaps may account for the unusual amount of vision in this particular case. Considering that the nystagmus is so well marked it would be interesting to know (1) the condition of the choroid, and (2) the visual acuity of the patient.

I am, Sirs, yours faithfully,

R. BRUCE FERGUSON, M.A., M.B. Cantab.

Feb. 2nd, 1895.

"THE DENTIST'S EDUCATION."

To the Editors of THE LANCET.

SIRS,—With one point, at least, in Mr. Newland-Pedley's letter in THE LANCET of Feb. 2nd I most cordially agree—viz., that the Royal College of Surgeons should hold an examination in dental mechanics which all dental students should be compelled to pass before entering a hospital for their further training for the L.D.S. This previous examination in dental mechanics would ensure the due attention of students to this important subject, and would compel practitioners receiving pupils to see that the instruction which they profess to give becomes a fact instead of fiction, and in the event of their neglect it would be known with whom the responsibility rested. At the present time students may be rejected at the end of their hospital career because that which they should have learnt before they joined a hospital at all was never taught them, and the hospital becomes discredited unfairly, while it is impossible for parents to know with whom the responsibility really lies.

I am, Sirs, yours faithfully,

STOREB BENNETT, F.R.C.S. ENG., L.D.S., &c.

London, Feb. 5th, 1895.

CORONERS AND THEIR DUTIES.

To the Editors of THE LANCET.

SIRS,—You will greatly oblige by giving your opinions concerning the duty of a coroner in the following case. A short time ago I was asked by a midwife (unregistered), who attended the woman in her confinement, to see the body of a child which she said was stillborn. I examined the body, but refused to give a certificate of stillbirth as the child was

fully developed and there were no signs that it was born dead. The midwife informed me that the child was born "feet first." I communicated with the police, telling them that I could not certify and that probably the child died during the process of birth, and in my opinion if a medical man had been present the child's life would have been saved. This was reported to the coroner, who gave an order for burial, saying an inquest was unnecessary.

I am, Sirs, yours faithfully,

Feb. 4th, 1895.

JUS CIVILE.

THE REMUNERATION OF THE RESIDENT OFFICERS IN ST. BARTHOLOMEW'S HOSPITAL.

To the Editors of THE LANCET.

SIRS,—I have heard that within the past few months the governing body of University College Hospital have decided to board as well as lodge the resident house surgeons and physicians of that institution, and no longer to exact a weekly payment from them. I am under the impression that St. Bartholomew's is now the only hospital in London (and, I suppose, it is admittedly the most wealthy) where the resident staff have to board themselves. I am informed that although a house surgeon there is paid at the rate of £250 per annum for his services, yet during the six months in which he is in residence he is usually about £1 per week out of pocket for his board. If this be true, is it not a shame that these gentlemen, who give their time and very often their health, and without whose services the work of the hospital could not possibly be carried on, should be subjected to a system of what is little else than sweating? It seems to me a great pity that the governors of that institution have allowed smaller institutions, which are dependent on voluntary contributions, to be before them in making such a laudable reform in the remuneration of their officials.

I am, Sirs, yours faithfully,

Jan. 10th, 1895.

FAIR PAY.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Paupers' Food.

THE article in the *City News* of the 19th ult. has not been unnoticed. At the Prestwich Board one of the guardians said the worst day in the table was taken; but even then the cost should have been 3d. instead of 1½d., which would give 1s. 9d. for the week; and he stated further that the cost "solely for food and drink" was 2s. 3d. In a letter to the paper Dr. Boddy, the medical officer to the workhouse, stated that the books showed the cost per head was over 2s. a week, but that the number of young children who consume and receive less food than the adults, with also some infants at the breast, make the average cost for adults not much less than 2s. 6d.; and that the fact that the food is bought wholesale makes its amount considerably more than if it were bought at retail prices. Moreover, three ounces of tea instead of one and a quarter ounces are used to fourteen pints of water, and no soda is added. Pea-soup is given twice a week, and it is said not to be thin, but good. On four days meat and potatoes, and on Sundays bacon, potatoes, and bread, are given; and a few years ago new milk was substituted for skim milk. At the Salford Board the chairman of the workhouse visiting committee maintained that "margarine was better than lard butter," and that it cost more than 6d. a pound. There was some difference of opinion as to the tea, the chairman saying it was good enough for him, and that the old people preferred it without milk. Another of the guardians took a more generous view: "It was no use saying the tea was good" with eight pints of water to an ounce of tea, and he would reduce the water to six pints. Indeed, he considered that the paupers should be treated "like ordinary Christians," and should have milk in their tea. The recent circular of the poor law board is so humane and considerate in tone that it seems as if for the sick and aged the days of penal severity may come to an end as soon as the guardians, or at least some of them, have grasped the idea that old age and sickness are not criminal.

Medico-Ethical Association and the Midwives' Diplomas.

A special meeting of this association was held about ten

days since to consider the action of those members who still grant diplomas or certificates to pupil midwives, the effect of such action on the training of medical students, and to decide the course to be adopted. After a long and somewhat heated discussion, a resolution condemnatory of the giving of these documents was passed by a large majority. Although many of the consultants, or specialists, as they are too often designated, are members of the association, general practitioners are the most numerous. The latter contend that this movement is ruining their midwifery practice, the importance of which as the surest stepping-stone to family practice has long been acknowledged. This is believed to be due to the multiplication of midwives by the temptations and encouragements thrown out to women to take up this branch of the profession after a training of three months. According to the testimony of those acquainted with some of these women the training must be in many instances scanty in amount and the knowledge acquired very superficial, consisting largely of learned phrases, not always apposite, but well calculated to impress those more ignorant than themselves. Some have advertised in the papers that besides attending midwifery they treat the diseases of women and children. All this is distinctly asserted; but, even allowing for some exaggeration, it discloses an evil pretty sure to accompany the good the authors of the new order of practitioners no doubt sincerely hope for. The general practitioners deny the need of so many midwives, though they appreciate the value of good nurses. Much correspondence (not calculated to raise the profession in public estimation) has been going on for months past in the Manchester papers. Most of the letters are anonymous, some purporting to come from members of the profession, others from laymen, and some from midwives. The Professor of Gynecology in the Owens College has written long letters to the papers, advocating what is called the professorial view that this action is philanthropic. The general practitioners, on the other hand, feel sorely aggrieved, saying that it is taking the bread out of their mouths and is no boon to the poor, but is fraught with danger. Just now feeling runs too high for calm and dispassionate treatment of the question. The spectacle is not edifying, even to a looker-on belonging to the profession, and the lay spectator may be forgiven if he should feel some contempt for a divided profession carrying on its squabbles in public.

Manchester Eye Hospital.

The seventy-ninth annual meeting was held on the 23rd ult. At the out-patient department in John-street 11,972 patients attended, an increase over the previous year of 1405; at the Oxford-road Hospital 9603, an increase of 1269: the total being 21,575, showing an increase of 14 per cent. There were also 1336 in-patients, against 1315 in 1893. The average stay in hospital was twenty days and three-quarters. The accident cases at the two places were 3020, against 3234 in the previous year. The benefits of the institution are freely sought by patients from the neighbouring towns. The chairman said that in 1889 the number of patients was over 15,000, but now they had "achieved the grand total of 21,575"—a number, he believed, reached by no other hospital except that of Moorfields in London. Mr. W. H. Holland, M.P., said "there was a surprising need for the institution, as was shown by the fact that the out-patients showed an average of 70 per day." These statements show that crowds of people are ready to make use of the hospital, but whether they suggest an abuse of the charity is another question. The lay board of a hospital is no doubt influenced—often unconsciously—by the feeling that the institution must be made a success; and this can best be made clear by the number of patients that can be cited at an annual meeting, showing what a "grand total" has been "achieved." Among the 21,575 out-patients, how many were suffering from trivial affections such as any qualified practitioner could treat, and how many could have afforded to pay his modest charges?

Medical Evidence at Inquests.

A question arose at the conclusion of an inquest yesterday on a case of poisoning by an overdose of chloral which is of some interest. The medical witness was asked by the coroner why he did not give assistance to the officer who was sent to him for information in order to prepare his report. The witness said he had done so. But it was objected that he would not state the cause of death, to which the answer was that on two previous occasions when he had done so inquests

were held, but no medical evidence called. The coroner spoke about spending the ratepayers' money, and said: "If we can do without a doctor we always do." The witness maintained that he did give assistance to the officer, and that the information he withheld could be best given at the coroner's court. Is it fair to a medical man to obtain from him gratuitously information that will enable the coroner to do without his evidence?

Feb. 5th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

"Should Doctors Dispense?"

UNDER the above title an animated discussion has lately been carried on in one of the local evening papers. The origin of the controversy was a case which occurred in London. It is notorious that chemists will prescribe for patients over the counter, an abuse which it is difficult to prevent as long as the public choose to adopt this form of getting medicine for their ailments. As a rule, no doubt chemists act carefully and intelligently, but the evil remains as to the mode of doing so. The reasons against medical men dispensing their own medicines are urged with more coarseness than candour—that the power of giving death certificates might be used to cover any fatal mistake; that they have not a sufficient knowledge of dispensing; and, lastly, the liability to substitute cheap drugs for more expensive and efficacious ones. As usual a middle course reveals the truth. It is impossible for a medical man living in a rural district to avoid dispensing his own medicines. In large towns the competition among medical men who do their own dispensing renders it a necessary part of their living. In better-class practices the same excuses do not hold good, and the principle of each sticking to his last will enable the medical practitioner to prescribe and the chemist to dispense, with the mutual good understanding which generally prevails.

Hospitals and the Voluntary System.

At the annual meeting of the Children's Hospital, held on Jan. 28th, the President, Lord Cobham, made some interesting observations upon this subject. He was afraid that unless these institutions received more liberal support the voluntary system could not go on much longer, and the State would have to step in and undertake the management. He mentioned also that the new death duties would probably influence the direction of contributions. I am inclined to think that the views thus expressed are somewhat too depressing, and that, making allowances for bad trade, scarcity of money, and the rapid increase of population, this aspect is too severe for general acceptance. In this city the charities are doing fairly well under the circumstances. In this particular hospital, thanks to the energy of the committee, the subscription list was raised last year by about 10 per cent. The amounts vary in different years to individual institutions, and there is no doubt that fresh sources of income must be found to meet the requirements of each. Increased activity in collecting, an aptitude in reaching the large class outside the usual subscribers, will do much towards raising additional funds. It will be a disastrous time when the experiment of handing over our hospitals to the State is tried, and the cheerful giver is supplanted by officialism and rates.

Registration of Midwives.

A special meeting of the Birmingham Branch of the British Medical Association was held on Jan. 31st to receive, *inter alia*, the report of the committee on the registration of midwives. A considerable amount of discussion took place, and in the end the report of the committee was rejected. The fate of the midwives was an adverse one; probably with some alteration in the propositions laid down another attempt to secure the adoption of rules for their efficiency and regulation may be more successful. At present the local feeling is certainly that of opposition to any scheme in which the effort to supply the needs of this branch of practice is taken from the rôle of the ordinary medical attendant.

The Wyld Green Poisoning Mystery.

On Jan. 19th I gave a *résumé* of this remarkable series of cases of poisoning, and stated that at the coroner's inquest Mr. C. W. Iliffe, the coroner for North Warwickshire, recommended that an expert should be asked to assist the medical

man in deciding as to the cause of death. The following is Dr. Klein's report upon a sample of the soup which appeared to have been the active agent in spreading the poison:—"I beg herewith to report on the results of the examination of the sample of soup submitted to me. I. On Jan. 24th I received a glass jar of fluid material, tied with a membrane. The material in the jar had, on opening, a sour smell and gave a strong acid reaction. It was a thick fluid, containing various vegetables, fat, and bits of flesh. Under the microscope besides these substances there were seen a multitude of microbes—in fact, the whole material was crowded with them. Amongst them could be recognised various forms of bacilli, differing from one another in length, and numerous yeast cells. II. Cultivations were at once made so as to isolate the microbes. These cultivations yielded the following microbes in colonies: 1. Torula, a yeast very copiously present. 2. A short non-motile bacillus, not liquefying gelatine, fairly abundant. 3. A bacillus which proved on sub-culture to be closely related to the bacillus coli. This microbe is a normal inhabitant of the bowels of man and animals, and is a prominent microbe of sewage. In the soup it was present in considerable numbers. 4. A bacillus which also proved on sub-culture to be closely related to the bacillus coli, but must be considered as a variety of the typical bacillus coli. It is also a normal inhabitant of sewage, and was present in enormous numbers in the soup. III. Experiments were made with the soup and with the cultivations obtained from it: (a) Feeding of mice with the soup produced no ill effects. This does not prove much since the time that had elapsed since the consuming by human beings at Wylde Green and the experiments made here was considerable; and it is known that organic substances poisonous at one time lose their action when exposed to additional fermentative changes. (b) Inoculations of guinea-pigs with the cultures of microbes Nos. 3 and 4 (bacillus coli and variety) prove these microbes to be virulent, microbe 4 was particularly highly virulent. (c) Inoculations of guinea-pigs with microbes 1 and 2 had no ill effects. (d) Microbe 4 multiplies extremely rapidly in beef broth kept at body temperature—i.e., about 37°C. It turns the broth very turbid in twenty-four hours, the broth being filled with the microbe. In addition there are present by this time numerous flakes and flocculi entirely made up of the bacilli. If such a broth culture is subjected to filtration, by which the bacilli are separated from the fluid, and when this latter is injected in small quantities (0.05 c.c.) into guinea-pigs, it is found that these die in from six to eight hours under symptoms of acute poisoning. From this it is then clear that this microbe is capable of forming rapidly in broth poisonous chemical substances. IV. Conclusions.—From the foregoing observations the following conclusions can, I think, be drawn. 1. The soup contained microbes which were derived from sewage; it is, therefore, highly probable that the soup had been polluted with sewage. 2. Amongst the microbes present in the soup the bacillus mentioned (sub 4) as a variety of the bacillus coli is possessed of virulent properties on account of its extremely rapid multiplication at the body temperature and the poisonous substance which it elaborates in broth culture. It is most probably this microbe which caused in the consumers of the soup the ill effects and the disease. This bacillus, it will be remembered from the foregoing paragraph, was present in the soup in enormous numbers."

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Appointments to the Scottish Lunacy Commission.

It is with much satisfaction that we in Scotland have received the news of the appointment (already announced in your columns) of Dr. Fraser as Assistant Commissioner in Lunacy to the Commissionership rendered vacant by the resignation of Sir Arthur Mitchell. When Sir Arthur Mitchell's resignation was intimated it was pointed out in these columns that the vacant commissionership ought to be filled by the promotion of Dr. Fraser. It was feared that political considerations might unduly influence the appointment. I do not profess to be acquainted with the political bearings of this appointment—if there are any; but it may safely be said that to the profession as a whole Dr. Fraser's appointment is most satisfactory. His work as deputy commissioner has been done with zeal and enthu-

siasm and with that kindly and judicious consideration for patients and their friends which is so desirable in anyone holding such a post. Dr. Fraser was a distinguished student of the University of Edinburgh, being one of the two best men of his year. After graduation he became assistant medical officer to the Fife and Kinross Asylum, and some years later superintendent. In that position he showed great administrative ability and tact, and when a vacancy occurred on the Commission by the retirement of Dr. Paterson, Dr. Fraser was appointed an assistant commissioner in 1877. Part of his duty in this capacity has been to visit boarded-out lunatics in many of the most outlying parts of the Highlands and islands, duty implying a good deal of arduous work, travelling, and exposure. The post rendered vacant by Dr. Fraser's promotion has been given to Dr. J. F. Sutherland, medical officer to the Duke-street Prison, Glasgow, who is also a graduate of Edinburgh University. Dr. Sutherland is secretary to the departmental committee on habitual offenders, vagrants, and inebriates which lately sat in Edinburgh, and he has taken an active interest in, and has written upon, hospital construction and management, dipsomania, and allied topics.

St. Andrews University and the Medical Education of Women.

A correspondent, who writes as if he were well acquainted with St. Andrews affairs or inspired by someone in touch with the inner workings of that University, has written to one of the Scottish newspapers on the subject of the medical education of women. He says that at a recent meeting of the University Court it was proposed and carried: "That two chairs be founded at St. Andrews and endowed out of the Berry bequest, to be called respectively the Berry Chair of Anatomy and the Berry Chair of Materia Medica, with a view to giving two complete *anni medici* at St. Andrews." Mr. Berry, whose name is attached to these proposed chairs, left a legacy of £100,000 to the University. The correspondent says that it has been felt for years that it was important to develop not only medicine, but also science, at St. Andrews. The medical and science chairs at present are chemistry, natural history, physiology, natural philosophy, and mathematics, and a lectureship on botany. If to these were added a chair of anatomy and another of materia medica the medical and science chairs would be eight in number. The facilities for studying the fundamental subjects in medicine and science at St. Andrews could not, it is held, be surpassed. The distance between St. Andrews and Dundee is found to be an insuperable barrier to having the St. Andrews medical and science school located wholly in Dundee. Not a few of the divinity and arts students are desirous of studying medical and science subjects at St. Andrews for the purpose of general culture, and it is right and reasonable they should have opportunities for so doing. Comments are then made to the effect that the affiliation of Dundee with St. Andrews had been a failure. It is pointed out that, according to the ordinances recently issued by the Universities' Commissioners, two years of university residence are required on the part of all those who aim at graduating in medicine in any of the Scottish Universities, it being provided that the remaining three years can be taken at any recognised medical school in Great Britain or Ireland. Other reasons for extending medical teaching at St. Andrews are that quite recently fifteen medical bursaries, each of the annual value of about £30, have come to the University, and are designed for lady medical students at St. Andrews and cannot be transferred to Dundee or elsewhere. To this is added the fact that a spacious residential hall is about to be built for lady students attending the University, so that it is regarded as the bounden duty of the University to make an effort to supply the necessary medical teaching for at least the two residential years. No objection can well be made to this scheme. St. Andrews cannot ever be a fully equipped medical school, for it has no facilities for clinical teaching, and if it prefers to try to attract students for a couple of years, rather than have a fully equipped school at Dundee, no objection need be made to it. As a matter of experience schools which only provide a partial curriculum are not successful, and now, both in Edinburgh and in Glasgow, a full curriculum is provided for female medical students, which allows them to graduate at the university of the city in which they have studied.

Public Health at Glasgow: Small-pox and Vaccination.

The most alarming feature in the public health of Glasgow just now is the rapid and very considerable spread of

small-pox. Starting about a month ago with five cases (all in one family), there are now (Wednesday) thirty-nine cases in hospital, most of them severe. As many of the patients worked in a rag store suspicion was at first directed to the rags with which they worked as being the source of the infection. This view has now, however, been given up, the disease having been carried by one of the first cases to the store in which she worked. This outbreak is the largest and most important we have had in Glasgow for a good many years. It started in a family whose history affords a good object lesson in the value of vaccination. The family in question is a respectable one, living in a house of three apartments; the ages of its members and their condition as to vaccination are as follows: Father, fifty-two, vaccinated; mother, forty-eight, had small-pox in infancy; grandmother, seventy, vaccinated; son, twenty-seven, vaccinated; daughter, twenty-one, vaccinated; daughter, twenty, vaccinated; daughter, eighteen, vaccinated; daughter, fourteen, unvaccinated; son, twelve, vaccinated; daughter, eleven, unvaccinated; daughter, six, unvaccinated; grandson, four, unvaccinated. The last to be vaccinated was the boy aged twelve, who shortly after developed hydrocephalus; he is at present a dwarfed child, almost perfectly helpless, with a very large head. As this illness was attributed to vaccination the parents would not allow any of their other children to be vaccinated. As far back as Dec. 7th one of the girls (vaccinated) fell ill, developed a few spots, but after ten days at home she returned to work. Then the four unvaccinated children sickened in succession, and were removed to hospital, where one died from malignant small-pox and the others are struggling for their lives. As this infected family were in unrestrained intercourse with the public from Dec. 7th till about Jan. 9th the extent of the present outbreak need not be wondered at. Amongst the later cases was that of a friend of the family; he was said to have been vaccinated in infancy, but he presented no mark of the operation; he died shortly after admission to hospital. This history gives a good illustration of the basis on which much of the popular prejudice against vaccination rests. The hydrocephalus, which, like many other allied diseases, is apt to appear in the first year of life, had nothing to do with the operation; it led to the abandonment of vaccination in this particular family, however, rendering it a standing danger to the whole community, and causing lasting grief and regret to the parents, who were themselves protected.

Feb. 5th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Outbreak of Small-pox in Dublin.

In consequence of this contagious malady showing no abatement in Dublin the Public Health Committee have adopted a resolution to the effect that, having heard Sir Charles Cameron and Mr. Stafford, Local Government Board inspector, and having given the question of the prevention of the spread of infectious disease every consideration, this conference is of opinion that in the interests of public health provision should be made for the isolation of such infectious disease by the erection of one or more hospitals to be wholly devoted to the reception of such cases. It is proposed that these hospitals shall be erected in some rural district distant from any populous centre and that thereafter no infectious disease shall be received into any of the existing hospitals in Dublin. The above resolution has been recommended to the serious attention of the urban and rural sanitary authorities of Dublin and surrounding townships, with a request that they should nominate representatives to attend any future conferences convened by Sir Charles Cameron.

Health of Dublin during December.

Sir Charles Cameron in his report on the state of public health in Dublin for the month of December states that as compared with the previous month the mortality caused by small-pox was more than double—viz., 26. There was an increase in the fatal cases of typhoid fever, diarrhoea, dysentery, and whooping-cough. The death-rate was 3.85 per 1000 below the mean rate for the corresponding month in the previous ten years. Notwithstanding the epidemic of small-pox the zymotic death-rate was only 0.53 in excess of the mean rate for the month. The epidemic of small-pox continues, and, no doubt, will continue during at least the winter months. It had nearly died out upon the north side

of the city, but it now appears to be on the increase there. During the month cases of small-pox were admitted to hospital from thirty streets on the north side and ninety-six on the south side. Everything has been done to limit the spread of the disease. At present there are no fewer than fifty-six men and women occupied in the removal of patients to hospital, in disinfection of clothing and bedding, and in the disinfection, whitewashing, and cleansing of infected dwellings.

The Battle of the Clubs at Cork: the Benefit Societies.

A meeting of the members of the different lodges of the Oddfellows was held last week for the purpose of electing a medical officer for the Munster, City of Cork, Commercial, and Hibernian Lodges. After some discussion it was decided to elect two medical officers instead of one. Applications were received from Mr. M. J. Cahalan, Nenagh, Mr. James McLoughlin, Dr. Joseph Alexander O'Sullivan, Dr. M. A. Morris, and Dr. W. McMath. Mr. McLoughlin and Dr. O'Sullivan were proposed as medical officers and unanimously elected. A meeting of the Roman Catholic Young Men's Benefit Society was also held to elect a medical officer, when, on a poll, Dr. J. A. O'Sullivan was successful by a majority of twelve votes. The following resolution was adopted unanimously: "That the best thanks of this society be conveyed to Mr. Maurice O'Connell for his unfailing kindness and attention to our members while acting as medical officer of the society, and we regret that the new rules of the medical profession oblige him to sever his connexion with us."

The Battle of the Clubs at Cork: the Attitude of the Chemists.

One of the most noteworthy incidents during the week in connexion with the club fight has been the action of the chemists. I must explain that the majority of the club medical officers in Cork have not been in the habit of supplying medicines, and a contract was generally entered into by the club with one of the local druggists. The rates varied, but latterly 5s. per family per annum was the lowest sum paid to the druggist. However, "example is contagious," and the druggists, finding that it was not merely poor working men they were dealing with, decided that the gentlemen members of the clubs should pay for their drugs on the same terms as anybody else. To accomplish that end the druggists, like the medical men, were obliged to include all club members unless the clubs should think fit to exercise reasonable discrimination in the admission of members. This action of the druggists, whilst helping themselves, must necessarily prove a very severe blow to the clubs in their fight with the medical men. To understand the full bearings of it it must be looked at in this way. The minimum charges asked by the medical men were 7s. 6d. and 15s., according to income. Five shillings added for medicines would make 12s. 6d. and 20s. respectively. Now the member of the club gets no reduction on his medicine bill, which at the end of a few weeks' illness would amount to a very respectable figure. I wonder how soon the poorer members of the clubs will fully realise how dearly they are paying for their chivalrous defence of the rich men's meanness. Will the richer members give their employees an increase of wages to meet the increased cost of the medicine bill?

Health of Ireland.

During the quarter ended December last the births registered amounted to 24,977, equal to an annual birth-rate of 21.7, and the deaths to 18,799, or 16.3. The birth-rate in Ireland for the quarter was 0.4 over the average rate for the corresponding quarter of the past ten years, and 0.5 over the rate for the fourth quarter of 1893. The deaths were below the last quarter of 1893 to the extent of 3117. Compared with the returns of pauperism for the corresponding quarter of 1893 there is a decrease of 691 in the average number of workhouse inmates on Saturdays during the quarter, and a decrease of 1439, or 2.5 per cent., in the average number of persons on out-door relief. Measured by the mortality, the state of the public health must be regarded as satisfactory, the death-rate (16.3) being exceedingly low, and there has been no general prevalence of any zymotic disease. Small-pox caused numerous deaths in Dublin, but it appeared in only a few other localities, and but one death occurred outside the Dublin district. Whooping-cough was prevalent in several districts, and the mortality therefrom was above the average, as were also the deaths from scarlet fever and diphtheria; but, on the other hand, there was a decline in fatal cases of measles, typhus fever, enteric fever, simple continued fever, and diarrhoea.

Feb. 5th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Fetid Endometritis of Old Women.

ENDOMETRITIS occurring in women after the establishment of the menopause is doubtless due in some instances to the reawakening of an old infectious process or to a necrobiosis accompanying the elimination of a moderate-sized fibroma; but these causes cannot explain other cases. Thus, Fritsch,¹ and, later, Patru,² ascribe its occurrence to a destruction of the endometrium. In some of these sufferers the symptoms recall those of cancer of the uterus—vaginal irritation, periodic flow of pus, emaciation, and straw-coloured complexion. The importance of a correct diagnosis in such cases has impelled Dr. Maurange to publish three observations of the disease, for a description of which classical works on gynaecology may be vainly thumbed. The first case was that of a woman aged fifty-five, in whom menstruation had ceased at fifty. For the past few months she had lost flesh, the features were drawn, and the complexion yellowish. She complained of abdominal pains, with a constant discharge of a horribly fetid, thick liquid—so great was the stench that her *femme de chambre* could not bear to remain near her. An examination by Drs. Piqué and Josias, surgeon and physician respectively to the Paris Hospital, led to the diagnosis of cancer, despite the smallness and mobility of the uterus and the absence of lesions of the os. Hysterectomy was proposed and accepted, but fortunately for the patient the os was first dilated with laminaria, the removal of which gave exit to a flow of pus, floating in which were fragments of mucous membrane. Examination of one of the fragments failing to confirm the diagnosis of malignant disease, the uterus was thoroughly scraped, with the result that recovery ensued in a month. Two years later her appetite had returned, the complexion was normal, and all pains had ceased. The other two cases cited were similar to the first. It would appear that the disease occurs in women from five to fourteen years after the onset of the climacteric, that it attacks women who have had children as well as those who have never been pregnant, and that pathological antecedents have no appreciable influence on its occurrence. The symptoms are as detailed above, and, in addition, the sound enters for a distance of from seven to eight centimetres; its introduction is painful and its removal induces a copious flow of bloodstained pus whose fetidity surpasses even that of cancerous ichor. Only histological examination of debris collected by curettage can enable us to distinguish between this disease and cancer. In only one instance has this examination been made (by Dr. Maurange). The lesions discovered were those of chronic catarrhal endometritis—viz., glandular hypertrophy, leucocytic infiltration, and areolar hyperplasia. Macroscopically the uterine mucous membrane is swollen, hardly ever ulcerated, and is easily detached with the curette. The prognosis is favourable if the following treatment be carried out: dilatation of the os and thorough scraping of the uterine lining, followed by *tamponnement* of the uterine cavity with iodoform gauze.

A Cheap and Efficient Disinfectant for the Sick-room.

The fetid exhalations emitted by the faeces are a source of great annoyance to patients condemned to a prolonged sojourn in one room, as is the case in, for example, typhoid fever. M. Meillère strongly recommends the following powder as an efficient and very cheap deodorising and disinfecting agent: sulphate of zinc, 1000 grammes; sulphuric acid, 5 to 10 c.c.; essence of mirbane, 2 c.c.; colouring matter (e.g., indigo blue), 15 centigrammes. About five grammes of this salt are placed in the bedpan before it is used. Contact with urine or liquid stools determines prompt solution of the salt, deodorisation is instantaneous, and the liquid excreta are at once sterilised. The fetor is transformed into a rather agreeable odour. The employment of this method allows, also, of the preservation of the excreta for microscopical examination.

Antitoxin Gossip.

Notice is given that, after the 10th inst., practitioners and the police desirous of procuring anti-diphtheritic serum must apply, not to the Pasteur Institute, as at present, but to pharmacists, who will then be the exclusive *dépôtaires* of

the precious antidote. The poor of Paris and the provinces will be supplied gratuitously through the Assistance Publique and analogous provincial bodies, the distribution being regulated by rules formulated by the Comité Consultatif d'Hygiène Publique de France and the Administration. Meanwhile, the readers of THE LANCET will be glad to have fresh statistics bearing upon the efficacy of the method in the diphtheria wards of the Hôpital des Enfants Malades. Thanks to M. Lebreton, I am to-day enabled to communicate the results of three months' application of Dr. Roux's method at that institution. At first the little patients were located in two wards—one for each sex—and in a common room where cases in which other germs in addition to Löffler's bacillus had been discovered were isolated. There have been erected since wooden pavilions, and the accommodation is correspondingly improved. In each case an injection of serum was invariably practised before the diagnosis was bacteriologically settled. It would appear that the energy of the antitoxin has increased, for smaller doses are now given than formerly. Of 330 children, 258 of whom were recognised as diphtheritic and treated solely with antitoxin and tonics, 31 died, giving a mortality of 12 per cent. Subtraction being made of 8 who died within twenty-four hours after admission, and without having had time to undergo the treatment, the percentage of deaths is diminished to 10.8. Twenty-four tracheotomies gave 9 deaths (37 per cent.), and 51 out of 60 intubations necessitated by diphtheritic croup yielded a mortality of 27.45 per cent., due to broncho-pneumonia or bronchitis already existing when the antitoxin treatment was instituted. The *contretemps* determined by the injections were, (excluding one case of local suppuration due probably to a *lapsus* in disinfection): 1. Eruptions, principally urticarial, less frequently scarlatiniform or mealy, and (twice only) polymorphic, accompanied in ten instances by an elevation of temperature above 102.2° F., this hyperthermia appearing to be caused by the employment of certain specimens of antitoxin. 2. Albuminuria, observed in 140 subjects. In 57 of these the phenomenon appeared late, as if it constituted an effort of elimination coinciding with recovery. Post-diphtheritic paralysis is said to be rarely met with, but figures are not supplied. Intubation is said to be less harmful than formerly, seeing that the injections allow of the more early removal of the tube. In many cases of pure diphtheria the removal was effected in forty-eight hours; its average sojourn was from three to five days, the guide being the cessation of the reproduction of false membranes. In 7 cases the tube had to be removed owing to its becoming obstructed either by membrane or by the string, which is only left attached in the case of children under one year and a half old. Seven times the tube was expelled in coughing, but it was not always necessary to reinstate it. In every case it is necessary to obviate the drying of the inner wall of the tube by the action of the steam spray kept going near the patient. Once the extractor used for the removal of the tube got loose and the tube was swallowed, to be later on expelled per rectum without any harm resulting. Sometimes removal of the tube is followed by spasm of the glottis, necessitating a fresh intubation. The possibility of these accidents impels M. Lebreton to give the preference in private practice to tracheotomy, intubation being reserved for hospitals. But even in the wards he believes tracheotomy to be preferable when grave asphyxial symptoms supervene. M. Lebreton does not appear to be in favour of antitoxin used prophylactically.

The Antitoxin Treatment of Diphtheria.

No less than three meetings of the Society of Physicians of Vienna were taken up by a discussion on this subject, but it cannot be said that anything new has been brought before the profession as a result. The majority of the speakers were in favour of the treatment, and the opposition raised by Professor Kassowitz was more a criticism of the scientific value of Behring's discovery than a report of his own personal experience, which he confessed extended only over eight cases. These cases all recovered, but Professor Kassowitz could not see that the improvement took place quicker than it might have been expected to do under any

¹ Handbuch für Frauenkrankheiten, vol. 1., p. 990.² Endometrite Purulente Sénile ou Endometrite Atrophique. Revue Médicale de la Suisse Romane, May 20th, 1893.

other treatment. The following figures illustrate the results obtained with antitoxin by the chiefs of the Vienna Hospitals: Primarius Gusendinger of the Rudolfs-Kinderspital had 27 cases of diphtheria, of which 11 died, the mortality being under 40 per cent.; the mortality from diphtheria before the antitoxin treatment had been 45·5 per cent. Primarius Heim of the St. Josef-Kinderspital had 27 cases of diphtheria treated by antitoxin, of which 6 died, a mortality of 22·6 per cent. From Nov. 4th to Dec. 18th last, when no antitoxin could be obtained, 32 cases of diphtheria were admitted to this hospital, of which 21 died, with a mortality of 65·6 per cent.; while from Dec. 18th till Jan. 10th 21 cases of diphtheria were treated by antitoxin, of which only 4 died, giving a mortality of 19 per cent. The mean mortality from diphtheria at this hospital during the last ten years had been 51·1 per cent., with the maximum of 58·7 per cent. and the minimum of 38 per cent. Professor Monti, of the Poliklinik, had treated 25 cases of diphtheria with antitoxin, and only 1 case has died. He drew attention to the fact that post-diphtheritic paralysis occurred in a high percentage of his cases, and said that in 7 cases he had observed erythema to follow the injections, so that he believed them to be not quite innocuous. Primarius Unterholzner, of the Leopoldstädter Kinderspital, had treated 30 cases with antitoxin, of which 8 died, the mortality being 26·6 per cent. When antitoxin could not be obtained, the mortality rose to 66·7 per cent. The discussion lost the character of a quiet scientific debate and became very personal at the last meetings. Some of the most eminent physicians in Vienna appeared to conclude as a result of the debate that medical men would do well to study more closely the pathology and symptomatology of diphtheria before entering into dialectics on the value of the antitoxin treatment.

Memorial to the late Professor Billroth.

A bust of the late Professor Theodor Billroth will be unveiled on Feb. 6th at a special meeting of the Society of Physicians of Vienna. Professor Albert will give an address on the occasion.

Medical Peers in Austria.

Professor E. Albert, the teacher of surgery of the Vienna University, and Professor Wiederhofer, the body physician of the Austrian Imperial family, have been appointed members of the Austrian Herrenhaus (Upper House of Parliament).

(FROM OUR OWN CORRESPONDENT.)

Annual Meeting of the Victorian Branch of the British Medical Association.

THE Victorian Branch of the British Medical Association has changed the date of its annual meeting from the first to the last month of the year, so that it no longer clashes with that of its rival, the Medical Society of Victoria. The report of the council for the past year was highly satisfactory, and the balance sheet showed a credit of £240. The following officers were elected for the ensuing year: President, Dr. Snowball; Vice-President, Dr. O'Sullivan; hon. treasurer, Dr. McAdam; hon. secretary, Dr. Mullen; council, Dr. Gresswell, Mr. Kenny, Drs. Meyer, Molloy and Snowball, and Mr. Springthorpe. The retiring president, Dr. Felix Meyer, read an able and scholarly address. After commenting briefly on the continued advances of bacteriology, the results of "serum therapeutics," with a passing allusion to the treatment of snake-bite by chloride of lime, Dr. Meyer dealt at some length with the present position of his own particular branch of medicine, that of gynaecology, emphasising the necessity for the gynaecologist being also a physician in the true sense of the term, as "a misguided enthusiasm for the surgical attack of women's ailments has, from time to time, not only caused a depreciation of the value of the gynaecologist in the eyes of the general practitioner, but has constituted him in the lay mind a *monstrum horrendum*, with the result that not infrequently the conscientious suggestion of operative measures is received by the patient with coldness and distrust, if not altogether rejected." Dr. Meyer suggested that, "seeing what remarkable changes are effected in the nervous functions of women by changes in her special organs, it would, perhaps, lead to light being thrown on cases of female lunacy if the observations of the resident medical officers at asylums

were supplemented by carefully conducted examinations by recognised authorities on the diseases of women." *En passant*, reference was made to the "new woman." "The growing girl," he considered, "educated in the elements of anatomy, physiology, and hygiene, can be taught to emancipate herself from the hurtful slavery of much that is fashionable in dress and custom without the possible danger of developing a three-volume novel or a fibroid tumour With a healthy nervous system and healthy bodily functions women may be safely left to determine for themselves the limits of their 'sphere.'" Dr. Meyer also deprecated "the element of sexual psychopathy which has been a marked feature of some recent novels. Tortured theories of heredity, exemplified by undesirable or impossible men, women, and children, can serve no good purpose and may give rise to harmful impressions." The address concluded with an eloquent peroration on the future of medical science, which, being truly evolutionary, will continue its great work towards the prevention of disease, and then with the process of time "the evils that flesh is originally heir to, or has since acquired, will have become matters of ancient history, and the natural decay of great old age will remain the sole disease."

Chloride of Lime in Snake-bite.

The merits of chloride of lime as a practical antidote to snake venom are being tested as cases occur. Mr. Hodgson reports one case in the *Australian Medical Journal* for December. The patient was bitten on the left forefinger by a snake two feet long. A ligature had been applied round the base of the finger and the wound well sucked. A 1 in 60 solution of chloride of lime, freshly prepared, was injected in doses of 20 minims into the finger, into the back of the hand, and the front of the wrist; 100 minims were injected into the arm, 60 minims into the right calf, and 80 minims into the right forearm. The injections caused great pain. The patient recovered. Mr. Mackenzie reports another case. The patient was bitten on the third left finger by a tiger snake. A ligature was applied to the base of the finger within ten seconds of the bite, but in ten minutes caused such pain and swelling that the patient removed it. Almost immediately he collapsed and broke into a cold sweat. His subsequent symptoms were dilated pupils, giddiness, with staggering gait, and dimness of vision. One hour after being bitten 30 minims of a 1 in 12 solution of chloride of lime, prepared for four days, were injected into the left leg, a little later 30 minims were injected into the right arm, and at intervals twenty-five injections were given in all in different parts of the body. The injections caused no local irritation, and the patient gradually recovered. Additional symptoms which developed during the case were, hiccough, vomiting of blood, double vision, swelling of the tongue, intolerance of light, and drowsiness.

Treatment of Hydatids.

Hydatid disease—its prevention and treatment—is kept pretty continuously before the profession in Australia. At the last meeting of the Medical Society of Victoria Dr. R. B. Duncan of Kyneton read a paper on a Series of Cases of Abdominal Hydatids, and introduced an interesting discussion on their treatment. Dr. Duncan in most of his cases followed the method known as Lindemann's. In performing this operation he insists on the necessity of partially emptying the cyst by a trocar before incising it, and fixing it to the abdominal wall, and that, when fixed, it is unnecessary at the time of operation to further evacuate the cyst. Instead of using a drainage-tube afterwards he packs the cavity with strips of iodoform gauze. He points out that ventral hernia is very apt to follow this method of operating, and hence cysts of moderate dimensions can be treated by complete evacuation and immediate closure, as recommended by Bond; while "in a not inconsiderable number of cysts free in the abdominal cavity partial or complete excision may be practised." In the discussion that followed several surgeons stated that in Bond's operation it was unnecessary to close the cyst with sutures, and confirmed the statement as to the liability to ventral hernia after Lindemann's operation. Mr. C. S. Ryan quoted a most remarkable case in which he had operated six times, and treated chiefly by Bond's method, modified by not stitching the adventitia, thirty-two cysts, five in the liver and the rest in the omentum and abdominal cavity. Several of the latter were excised entire. The patient had recovered, but still had two cysts remaining, one on the convex surface of the liver and one in the spleen. In the *Australasian Medical*

Gazette of December Mr. L. Fitzpatrick of Dabbo, N.S.W., records seven cases of hydatids. One was dissected out of the anterior triangle of the neck, and another from the fibres of the external oblique muscle of the abdomen. Another cyst was in the loin and presumably in the kidney, and was successfully treated by tapping and drainage. The most interesting case was one of intra-cranial hydatid, causing blindness, nystagmus, and frontal headache, and close to the upper third of the occipito-parietal suture a small, soft, pulsating swelling. On exploration the bone was found to be absorbed and the cyst bulged through the aperture. It was incised and the mother cyst extracted. It occupied the subdural space, lying over the second and third occipital convolutions, pressing the cerebrum forwards and the cerebellum downwards. The patient died a few days afterwards with frontal pain, paralysis, and fever. The *Australasian Medical Gazette* also, in an editorial article, advises that the health authorities should give more attention to the prevention of hydatids. Children as well as adults should be instructed as to the nature, mode of propagation, and means of infection of the disease. All dogs should be treated for tenia by being purged and dosed with areca nut and turpentine.

Medical Journalism in Australia.

The New South Wales Branch of the British Medical Association have decided to purchase the *Australasian Medical Gazette* from its present lay proprietor and make it the organ of all the branches of the Association in Australia. The other branches are to be supplied with the *Gazette* at a reduced rate, and will each appoint a local editor, but will have no monetary responsibility.

Suicide of a Medical Man.

Dr. Hood of Grafton, N.S.W., died suddenly on Dec. 26th, and it appeared that he had taken a fatal dose of hydrocyanic acid. At the magisterial inquiry it was found that the deceased committed suicide while temporarily insane. He had been melancholic for some time.

THE INDIAN MEDICAL CONGRESS.

THE SECTIONS.

SURGERY AND OPHTHALMOLOGY.

DEC. 26TH, 1894.

Presidential Address upon the Influence of Percival Pott, Syme, Simpson, and Lister on Modern Surgery.

[Surgeon-Lieutenant-Colonel Edward Lawrie, M.B. Edin., delivered his presidential address in the Section of Surgery. Commencing with an eulogium upon British surgery in India, and quoting the case of an ovariectomy successfully performed by one of his own pupils, who had for assistants three perfectly untrained laymen, he passed to the consideration of the subject of his paper, saying:]

"I have thought long and anxiously over the problem of the best way of occupying the time at my disposal for the delivery of the formal Address on Surgery before this, the first Indian Medical Congress. The conclusion I came to was that we cannot do better than consider the influence of four great British surgeons on modern surgery—Percival Pott, Syme, Simpson, and Lister. Percival Pott represents the surgery of the latter half of the eighteenth century. He resigned the office of surgeon to St. Bartholomew's Hospital in 1787. Syme and Simpson resigned their posts of professors of clinical surgery and of midwifery respectively in the University of Edinburgh nearly a hundred years later. Pott and Syme both served their schools, as Pott used to say of himself, "man and boy," half a century. In one of his well-known tracts Pott says: 'Our fathers thought themselves a great deal nearer perfection than we have found them to be; and I am much mistaken if our successors do not, in more ways than one, wonder both at our inattention and our ignorance.' Up to the time of Pott the state of surgery was imperfect. Operations were unnecessarily painful. The maxim *dolor medicina doloris* was accepted as fully demonstrated. Dressings were painful; the actual cautery was prepared as part of the necessary apparatus when the surgeon paid his daily visit to the hospital; and the natural processes of healing were either not recognised or disregarded. Pott's biographer states that he lived to see these remains of barbarism set aside and a more rational plan, of which he was the chief author, universally adopted. Pott was singularly successful with the trephine, and his

essay on Injuries of the Head is well worth careful study in connexion with the recent advances in brain surgery for which we are so much indebted to the splendid work of Ferrier and Victor Horsley. Pott discovered that, when the bone inflames after a blow on the head and a puffy inflammatory swelling makes its appearance in the scalp covering it, this generally indicates suppuration exactly opposite the same spot, on the inside of the cranium, which may be relieved by laying on the trephine. Pott published a most interesting and remarkable series of cases of head injury, numbers of which were lost from simple inflammation and pressure or from sepsis. There is very little doubt that most, if not all, of the cases to which I refer would have recovered if he had known the secrets of antiseptic surgery, which we shall see later he very nearly stumbled on to accidentally, and the modern use of antimony in the prevention of simple inflammatory conditions. When inflammation of the contents of the skull threatened to arise after injury of the head Pott's only available remedies consisted mainly of phlebotomy and the trephine, and he certainly used them most freely. Where he employed phlebotomy and the trephine in the cases of threatened intra-cranial inflammation we now use antimony, either in good big doses at long intervals or in small doses frequently repeated, and if it is a simple uncomplicated inflammation the antimony often cuts it short and saves the patient's life and obviates the necessity for an operation."

[Surgeon-Lieutenant-Colonel Lawrie then went on to mention the improvements introduced by Pott in the treatment of fistula in ano and internal hemorrhoids. Continuing, he said:]

"I much regret that time will only permit me to draw your attention to one more subject in surgery on which Pott left the record and stamp of his genius. I allude to *fractures*, and it is curious to note that almost every word he wrote on the principles of their treatment more than a hundred years ago is true to-day. He begins his tract on fractures and dislocations with the following quaint words: 'No part of surgery is thought to be so easy to understand as that which relates to fractures and dislocations. This is the opinion of a considerable section of the general public. They regard bone-setting as no matter of science; as a thing which the most ignorant farrier may become soon and perfectly master of; nay, that he may receive it from his father and family as a kind of heritage.' In the treatment of fractures Pott insisted on the importance of setting the fracture at the earliest possible moment after its infliction, and that it is wrong to wait for pain and swelling to subside, as these and other symptoms of the injury are due to, and are best remedied by rectifying, the faulty position of the broken fragments. But the pre-eminent principle we owe to Pott is that, considered abstractedly, neither extension nor counter-extension can even be necessary on account of the mere fracture—i.e., on account of the mere fragments of the broken bone, which if left to themselves remain just as motionless, just as absolutely still and with as little tendency to move, as these pieces of bone on the table. Pott showed that nothing can move the fragments of a broken bone but the muscles which are attached to them, and that the difficulty we meet with in making and in keeping up extension of the broken limb proceeds from the muscles only. To extend the muscles by putting the limb into that position which puts them into a state of tension is, if not to irritate them and cause them to offer resistance, at all events to give them their greatest power, whether of displacing the fragments of the broken bone or of opposing their reduction or setting. On the other hand, putting a limb into such a position as shall most relax the whole set of muscles belonging to or in connexion with a broken bone must best answer the purpose of incapacitating the muscles from acting upon it, and must remove the resistance they have it in their power to make attempts to reduce or set it. It follows that such a position of the broken limb as will best relax the muscles must be the best for setting the fracture and for keeping it set afterwards. A moment's reflection will prove to you that this is generally the position which the patient naturally puts a broken limb into in order to obtain ease until he gets proper assistance. The general position with regard to fractures then, comparing Pott's day with our own, is this: the obstacle to the setting of fractures is the action of the muscles. In Pott's time there were two available means of overcoming or counteracting this action—namely (1) extension, and (2) position; and Pott proved that extension is both unnecessary and painful. Modern surgery is armed with

three ways of doing the same thing—namely (1) extension, (2) position, and (3) chloroform. If extension is employed chloroform ought to be given in the setting of all fractures; but if position is relied upon—and it is entirely sufficient—the pain is so slight that chloroform is unnecessary in the setting of any fracture but the one exceptional fracture of the thigh. Not the least interesting feature in the connexion between Pott's principles of fracture treatment and modern surgery is the fact that the great surgeon himself once sustained a compound fracture of the leg. Amputation was decided on at a consultation of the St. Bartholomew's Hospital staff, and was within an ace of being performed when the opinion of one alone of the consultants prevailed and the limb was preserved. The fracture then united without inflammation, exactly like a simple fracture, and Pott attributed this happy result to the circumstance that when the protruding end of the broken tibia was reduced the valve-like opening of the soft parts closed behind it in such a way that the entrance of air into the wound was prevented, thus accidentally foreshadowing, a century in advance, the scientific aseptic method of the immortal Lister. In 1866, exactly 110 years after Pott's accident, which so nearly led him to the discovery of Listerism, Lister himself treated a compound fracture in the Glasgow Royal Infirmary by methodically preventing the entrance of air into the wound by means of an artificial scab of lint, blood, and carbolic acid; and in this way he opened up the new era which we call, and which is in truth, 'modern surgery.' The connecting link between Percival Pott and modern surgery is Syme. Pott died in 1783; Syme was born in 1799. Throughout his career, which ended in 1870, Syme upheld and consolidated Pott's surgical principles; but he was not the man to follow any beaten track, and during the fifty years he practised and taught he introduced many new measures into surgery which will perpetuate his name as long as medicine lasts. In 1823, when barely three and twenty years of age, he performed amputation at the hip-joint for the first time in Scotland; and in 1829 he excised the whole of the upper jawbone for the first time in Great Britain. A report of the latter case reached THE LANCET, and was published with the following editorial note in a bracket: 'We need no ghost from the grave to tell us what has become of the patient,' but a month later THE LANCET had the pleasure of recording his complete recovery. Syme established the operation of excision of joints in England; his operations on aneurysms have never been surpassed in boldness and originality; he showed that amputation of the whole arm with the scapula is a feasible procedure; and he was the first surgeon in England who successfully removed the whole tongue. It was not alone in great things that Syme excelled. It is to him that modern surgery owes the simplest and most perfect operation for harelip; the only faultless amputation known, that of the foot by the heel-flap; and the easiest and most lasting method of curing organic stricture of the urethra. With regard to Syme's amputation I need merely remind you that the tendency of all modern surgery is to make amputation flaps of skin. The next noteworthy phase of Syme's genius, which has had a remarkable effect upon modern surgery, was his almost intuitive perception of the cardinal point or essence, not only of an obscure case of disease, but also of new procedures and propositions in surgery. When Simpson brought *chloroform* to the notice of the profession Syme very quickly perceived the nature of its action and laid down rules for its administration, which have been proved by clinical experience and by the experiments of the Hyderabad Commission to be entirely sufficient when strictly followed to ensure the safety of the patient. Syme's rules are and I beg you will consider them well:—'The points we consider of the greatest importance in the administration of chloroform are: first, a free admixture of air with the vapour of chloroform, to ensure which a soft porous material is employed, presenting a pretty large surface instead of a small piece of lint or any other apparatus held to the nose; secondly, if this is attended to, the more rapidly the chloroform is given, the better, till the effect is produced, and hence we do not stint the quantity of the chloroform. Then, and this is the most important point of all, we are guided as to the effect, not by the circulation, but entirely by the respiration; you never see anybody here with his finger on the pulse while chloroform is given. We never continue the inhalation beyond the point when the patient is fully under the influence of the anæsthetic.' Finally Syme accepted and adopted Listerism as the perfection of

surgical science, in that it keeps away or removes from wounds every source of external irritation and contamination which can interfere with the natural processes of healing or cicatrization. The Listerian principle came to Syme as the most fitting termination of his labours in surgery, and he welcomed it with the quiet satisfaction of a successful general who has taken a leading part in an arduous campaign which ends in long anticipated victory. This brings us to the consideration of the direct influence of Sir Joseph Lister on surgery. However much the teaching of Pott, and later of Syme and his contemporaries, had led up to the antiseptic principle, or had, as it were, prepared the way for it, it came eventually as a surprise, and it revolutionised the surgery of the civilised world. The change was complete and final, though Lister has since improved his methods as the principle has been developed and circumstances have seemed to require it. The antiseptic method of Lister showed us exactly how to attain the very thing surgeons had been striving after for so long, but which no one had previously discovered. No surgeons had made greater efforts in this direction than the French. I spent the year 1869 studying medicine in the Paris hospitals, first in the service of Alphonse Guérin at the St. Louis Hospital, and later in that of Maisonneuve at the Hôtel Dieu. Alphonse Guérin thought he had discovered the panacea for surgical fevers and blood poisoning in lavish dressings of alcohol. He was undeceived by one of the worst outbreaks of pyæmia in the St. Louis Hospital which it is possible to imagine—one of his patients actually died from pyæmia after the amputation of a finger. Maisonneuve worked in a different fashion. His idea was that it was impossible to keep the germs of putrefaction, whatever they might be, out of wounds, and he therefore endeavoured to prevent organic fluids from collecting in them by exhausting them with an air-pump, which the patient had to work himself, and which was on this account impracticable. In other places it was hoped that by giving patients more cubic space in larger, better constructed, and better ventilated hospital wards success would be obtained. As to the value of this plan many of you may recollect what happened here in Calcutta. The Medical College Hospital was very nearly condemned as unfit for the treatment of surgical cases on account of inveterate pyæmia and erysipelas. At one time all the surgical patients were placed in tents; but, if anything, the erysipelas and blood poisoning were worse in the tents than they had been in the wards. All other attempts to successfully stamp out septic processes in wounds failed, and there is no more to be said about them than that they failed because they were not Listerism. The changes brought about by the introduction of the Listerian principle were mainly twofold—one immediate and the other remote. The immediate change was that hospitals in every part of the world, which had previously been considered unhealthy, became healthy under the antiseptic system, and it was found possible to keep surgical wounds absolutely free from sepsis and infection, no matter in what hospitals they were treated. The remote change effected by the Listerian principle in surgery is very ably explained in Watson Cheyne's paper on *Modern Methods of Wound Treatment* in THE LANCET of Nov. 17th, 1894."

[After some further remarks on Listerism the President passed to Sir J. Simpson and his application of the use of chloroform to surgery, and referred to the results of the Hyderabad Commission as proving that Simpson and Syme were right in their theories, and continued:]

"Finally, as you all know, the acknowledged safety of chloroform in India has been accounted for in various ways by our brethren in England. It does not appear to have struck them that the real reason for the safety of chloroform in this country is that for many years past the principles of Simpson and Syme have predominated throughout the whole of India; and it is not too much to state that the general adoption of these principles in modern surgery in future will alone render the benefits of Simpson's priceless discovery unlimited. Gentlemen, I have finished. I have endeavoured to bring before you this morning some of the principles of surgery which have been handed down to us by men like Pott and Syme. Their greatness and success as surgeons lay largely in their profound knowledge of anatomy, their choice of simple procedures and methods of operation, and their undivided responsibility for everything connected with the treatment of their patients."

The President concluded by an eulogistic reference to the medical profession in India.

PROCEEDINGS IN SECTION.

DEC. 28TH, 1894.

The following are abstracts of papers read in the section of Surgery and Ophthalmology :—

Vesical Calculus in India, its Distribution, and a Theory of its Cause.

Surgeon-Captain A. E. ROBERTS read a paper upon Vesical Calculus in India, its Distribution, and a Theory of its Cause. In this paper he said : "It has long been a commonplace of a certain rough-and-ready order of pathologists to assert the origin of vesical calculus in 'salts in the drinking water.' The theory commends itself by its beautiful simplicity; the patient takes in 'stone' at one end and passes it (or fails to do so) at the other, and makes as little demand upon the thoughtful intelligence of those who accept it as it received in the process of its conception. In the course of some observations on the chemistry of the excretions of natives of India I was struck by the fact, which runs counter to the routine doctrine of the schools, that the excretion of uric acid was far more marked in well-fed natives who never touch meat (or rarely) than in the ordinary European official living in this country. It then occurred to me that some one had attributed 'stone' in Norfolk to the excessive farinaceous diet of the people (? dumplings), and it was thought to be a promising subject to trace the incidence of the disease in its relation to diet in different parts of India, and on arriving at a definite fact of connexion to endeavour to explain cause and effect in physiological terms. Very roughly India may be divided into three great agricultural regions: 1. Extra-tropical India, the wheat region—the great plains of Northern India, where rainfall is moderate or small and the winter temperature comparatively low. This region almost corresponds with that lying north of the January isotherm of 65. The principal grains are wheat and barley. 2. The damper portions of tropical India, the rice country—all Bengal proper (including Assam), all the region north of the Krishna from the Bay of Bengal to the edge of the Trap country in the Deccan, together with the coast and delta lands of South India. 3. The drier parts of tropical India and all the black soil country, the millet region—besides the whole Deccan Trap area, with the exception of the west coast; this comprises all the black soil tracts of Southern India, and a very large proportion of the undulating red soil country. The principal grains are *jamari* (or *cholam*) and *chajra* (or *kambu*)."

[Surgeon-Captain ROBERTS then proceeded to give statistics of the various districts of India under grain cultivation, and continued:]

"Let us set down at once the relative incidence of calculus of the bladder in the various areas as above. The figures we give are the annual average prevalence of a varying number of years, as shown by all the various operations for calculus, and great care has been taken to search all available records, though these are in many cases very imperfect.

Different Areas of Hindustan in the order of "Calculus prevalence."

Area.	Proportion of population eating rice.	Rates of calculus operations per mille of population	Population in millions.	Average annual operations.	Remarks.
1. Punjab	$\frac{1}{2}$	0.078	19	1482	—
2. N.-W. P. & Oudh	$\frac{1}{2}$	0.021	45	925	—

Total annual average operations for all India					3041

"1. In British India, then, every year no less than 3041 calculi are removed from the bladders of natives, or rather 3041 operations for the removal of as many (and more)

'stones' are performed, and of this total nearly one-half occur in the Punjab. 2. The next point to note is that the order of calculus prevalence is in inverse ratio to the population eating rice as its staple food upon each area. 3. Where practically the whole population lives on rice as its staple food calculus disappears, as in Assam. 4. As we leave the coast areas and mount ever higher above sea level towards the interior calculus increases in prevalence. Though Bombay stands third on the list its coast area is very limited, the rice-eating population is small, and the calculus rate represents the high-lying millet region of the Deccan. We place a double contrast in view in the above sketch—(a) a contrast between the staple foods of certain defined areas; (b) a contrast between the sea-coast and the interior. What we here set ourselves to show is that vesical calculus in India follows as a result of the factors involved in this double contrast. A very interesting battle drama is constantly going on in the upper layers of the soil—a fight between carbonic and silicic acids for possession of the bases, sodium and potassium, and the result is that the sea accumulates all the sodic chloride, while the soil inland is robbed of this salt and contains little else than potassium salts (see Bunge). Now the amount of NaCl in any organism corresponds and varies with the amount in the environment. 1. Inland populations are, to a certain extent, battling with an unfavourable environment as regards the absence of the necessary salt, in which they originally developed; this also serves to explain the unconquerable desire which the great majority of people exhibit for salt in their food. 2. It explains the necessity for a liberal allowance of salt to children, our "embryological ancestors," if we may so call them, and the consequences of its deprivation will be the more apparent in pathological effects. The offices which common salt performs include—(a) The construction of organs; (b) it is the chief factor in the formation of gastric juice; (c) It dissolves 'globulins'; (d) The nitrogenous products of metabolism cannot be eliminated by the kidneys in the absence of chlorides."

[Surgeon-Captain Roberts then discussed with great care the dietetic value of sodium chloride, with special regard to the physiological chemistry of the body, and showed how absolutely necessary it is for vegetable feeders to have a free supply of salt. He went on:]

"The people who take salt, though differing in every other respect, are all characterised by a vegetable diet. In the same way those who do not use any salt at all are all alike in taking purely animal food. We have also seen that this urgent necessity for salt in vegetable diet depends upon the eliminating action of the excess potash salts, and if various food stuffs are compared in respect of this potash constituent it will be found that the proportion of potassium to sodium is highest in the very food staples on which the vast bulk of the Indian population is supported—that is to say, highest in all the common Indian food stuffs save rice."

[Surgeon-Captain Roberts then drew a parallel between the diets of a native and a European soldier, pointing out how deficient salt is in the former's dietary. He went on to tabulate the results arising in the human economy from a diet exhibiting insufficiency of NaCl, and proceeded:]

"Now the most important Indian diet stuffs—i.e., the cereals and leguminosae, not rice—yield urine which is as acid as that due to a meat diet, under normal conditions of digestion, because they are rich in albumen and phosphates and in calculus. The evil factors at work are, as we have shown, (1) the great amount of albumen and (2) the poverty of bases (due in great extent to deficiency of the common salt necessary, which are able to neutralise the uric and sulphuric acids formed from albumen). One more point as regards the liability of children to calculus. The amount of kidney excretion per kilogramme of body weight is far greater in children than in adults. Parkes gives the following statement:—

	In children.	In male adults.	Excess in children per kilogramme.
Water	59 c.c.	23 c.c.	36 c.c.
Urea	0.973 gram.	0.500 gram.	0.473 gram.
Urea and volatile salt...	0.279 "	0.151 "	0.128 "
Chlorine	0.308 "	0.106 "	0.202 "

1 Physiological and Pathological Chemistry.

Hence in children the amount of chlorine is three times greater than in adults (note, also, the excess of nitrogenous products), and hence the special necessity of extra NaCl and the special liability to concretions in children. Again, NaCl acts as absorbent, not only of crystalloids, but of colloids, fibrin, mucin, and albumen. Hence Jones first showed the solvent action of NaCl on urate of ammonium, and this is also the case with uric acid. One part of uric acid requires 8000 parts of water to dissolve at the body temperature, whereas the addition of $\frac{1}{2}$ per cent. of NaCl doubles its solubility, and 2 per cent. of NaCl quadruples its solubility (Plowright). Perfectly healthy urine should show no appreciable deposit; when it becomes concentrated (as it is liable to do in natives for reasons given) uric acid is thrown down as a urate. This may occur within the bladder, and the presence of a solid body in any part of the urinary tract favours depositions greatly. Dr. Goodhart has put it on record that the specially farinaceous feeders among children are those addicted to passing uric acid in abundance.² Lastly, Hirsch, in his great work on 'Geographical and Historical Pathology,' remarks on 'the mystery of the excessive prevalence of stone in the tropics,' while 'gout' is practically unknown. Now Dr. Haig, to whom I return thanks for much kindly personal help, has shown that the excretion of uric acid is greatly influenced by the comparative alkalinity or acidity of the blood, and that the amount of acidity may be made to vary within very considerable limits by the kind of food and by the process of digestion (as we have seen), as well as by the use of drugs. Uric acid in an acid blood tends to get stored in the spleen and joints, but when the blood is rendered alkaline (as we have seen it by deficiency of NaCl and excess of K) uric acid is dissolved out and excreted. We have then (1) greater tendency to formation of uric acid in natives, with excess of albuminates and their deficient metabolisms; and (2) very complete elimination of this uric acid by alkaline blood (due primarily to deficiency of common salt) as far as the bladder. The obvious result is that gout must be a very rare disease among the natives, because the alkaline blood stream never permits storage of the uric acid in the system or the joints. Sir W. Roberts³ draws attention to the effect of sleep and long daily fasts in increasing the amount of uric acid excreted, and these are assuredly factors in far greater play among natives in India with their fast from evening to mid-day and their somnolent habits than in Europe. The very common affection of enlarged spleen is another factor in the excessive excretion of uric acid. Pettenkofer found the normal average to be 0.872, while in a case of enlarged spleen it rose to 1.424 part in 1000. A case of a boy of sixteen years of age is recorded who excreted 18.28 grains daily, while his normal average should be about 6 grains. We have then perhaps an excessive production of uric acid by the factors at work just described, and certainly far more complete elimination of it from the body and tissues by the alkaline blood stream as far as the bladder. What, then, causes its deposition here? I do not think we can at present detail with certainty the steps in the process, which are doubtless varying and complicated. One important factor, perhaps, is the neutralisation of the acid sodium phosphate (the uric acid solvent) by the aromatic sulphates; and we know that the alkaline bases are diminished which go to neutralise the sulphuric and uric acids. My chief object to-day has been to draw attention to some important dietetic considerations underlying calculus formation in India. More intimate and sustained observation of the chemistry of the excreta may perhaps avail to clear up doubtful points, and piece together the scattered fragments of our little knowledge, and I hope in a fuller paper to throw some light on this important problem."

A Retrospect of Ophthalmology in Bengal.

LAL MADHUB MUKERJI, RAI BAHADUR, L.M.S., F.C.U., President and Teacher of Ophthalmology, Calcutta Medical School, and President of the Indian Medical Association, read a paper on the above subject. He began by saying that though ophthalmology as an exact science was as modern as bacteriology, as a crude art it was known in the East from very ancient times, and that although until recently Oriental practitioners knew no anatomy or physiology, yet they had treated successfully nearly all the best-known disorders of the human

eye. With this preamble he passed to consider modern ophthalmology in India and especially in Bengal.

"The history of modern ophthalmics in India dates from the establishment of the Medical College in Bengal in the year 1835. Prior to this a number of surgeons of the old Honourable East India Company's service had opened dispensaries in various stations in Bengal, notably in Calcutta, where the poor had their ailments gratuitously treated and often at the entire cost of these medical men. In these outdoor infirmaries, as they were called, there were a few beds for operation cases, and here Western medicine gained many of its earliest disciples, who became useful and distinguished practitioners. Not, however, until 1835—that is, on the opening of the Medical College Hospital in Calcutta—was any well-organised effort made to teach anatomy and physiology. Sixteen years later Western ophthalmics found an able exponent in Dr. Martin, whose appointment to the chair of ophthalmic medicine and surgery dates from the year 1851. His successors, Mr. Macnamara and Drs. Archer, Cayley, and Jones, have all been men of great ability, and have left brilliant legacies of their work behind them. Charles Macnamara, who is now one of the leading ophthalmic surgeons of London, gave India the first work of eye surgery and medicine based on Indian experience, and his book is still a valuable guide to our students, in spite of the gigantic strides that ocular therapeutics have made in the past two decades. I will deal briefly with some special points connected with ophthalmics in Bengal, and of necessity I can only touch the merest fringe of my subject, which has admittedly a very wide range. The world has been busy with ophthalmics, and never in the history of our profession has there been such a profuse display of knowledge and original research in ocular therapeutics as we have seen in Great Britain, America, France, Germany, and Europe generally at the present time. It is not my province to deal with new light and recent knowledge, but I am called on to sift the garnered grain of past generations, and to present, if possible, in a nutshell the work of others whose lives and records are now matters of history. In Bengal we have ocular diseases common to India generally, but I am concerned only with this province, and the limit of time and space remind me, and you also, of the duty of brevity. My remarks, therefore, will scan such familiar disorders as cataract, ophthalmia neonatorum, glaucoma, atrophy of the disc, and disorders of refraction and accommodation. The occurrence of cataract in Bengal is very common, and this may be judged by the fact that on an average nearly 300 operations have been performed yearly in the Eye Hospital of the Medical College during the past thirty years. The most generally performed and most successful method of operating for cataract in Bengal has been, and is still, by simple extraction of the lens without iridectomy, the pupil being previously dilated with atropine. The incision involves about one-third of the cornea and is made as nearly as possible in the sclero-corneal junction. There is much in success which depends on the individuality of the operator, and this cannot be exaggerated. Clean steady fingers and a delicate, dexterous touch, with a high moral appreciation of the responsibility, do more to make a record in successful ophthalmics than all the book reading in the world. I am able to corroborate this assertion by my own experience in watching the exceptionally able and dexterous operative work of my old teacher and friend, Mr. Charles Macnamara, a former professor of ophthalmics in the Calcutta Medical College Hospital. His modified linear extraction, which bears his name, involved no iridectomy. The pupil having been previously well dilated, his incision, so perfectly performed by a special knife of his own invention, left it an easy matter to introduce a scoop, and with a gentle pressure exerted upon the circumference of the lens caused it to be rotated on its axis to find a rest in the concavity of the scoop, and thus delivered from the eye with the least possible disturbance of the adjoining structures. The lens with its capsule entire so freed resulted invariably in the most perfect success of vision possible. Such, too, was the special individuality of Professor Henry Cayley of our College, whose operative work with cataract was extremely successful from the combined methods of Professor Macnamara and Von Graefe. The success of these two Calcutta ophthalmic surgeons gave a result of 87 per cent. of cures by Macnamara's method and 77 per cent. by von Graefe's. It is important in this connexion to state that these results were from hospital patients, in whom there was no choice of selecting suitable or unsuitable

² Brit. Med. Jour., Aug. 1st, 1891.

³ Croonian Lectures, 1892.

cases. The records of these surgeons in private practice, better where selection was the rule, yielded far better results, and a success of 90 to 95 per cent. was nearer their average. Personally, my experience during a practice of nearly thirty years, which has been guided largely by my association in work at the Ophthalmic Hospital for fourteen years with Mr. Macnamara and Drs. Cayley and Jones, has led me into selecting the operation for cataract usually performed by these surgeons combined and modified—that is, a von Graefe, —the sections being, however, purely corneal, and thus avoiding iridectomy in every possible case, and I may with gratification say that I have had results that equal those of my revered teachers. The operation which I have been accustomed to perform for many years past is preceded by preliminary antiseptic precautions. I wash my face and hands, and then cleanse the face, eyes, and eyebrows of the patient with cotton and a solution of boracic acid (one grain to an ounce of water), the lotion being freely put into both eyes while the patient is in bed. I now drop a freshly prepared 3 per cent. solution of cocaine into the eye to be operated on, which has already for two or three days been under the influence of atropine. The instruments are dipped in boracic lotion and then used. Special attention is paid to the knife, which is tested before operation as regards sharpness and polish. I use a stop-speculum. The section made by a Graefe's knife is corneal, and occupies nearly the upper third of the cornea. The left hand is used for the left eye and the right for the right. The section is completed by cutting directly through the cornea. It is so cut through that it allows the edges of the section to come directly together. I then take the curette and place it on the sclerotic at the lower part near the corneo-sclerotic junction and deliver the lens by pressure. I allow a little time to elapse, if necessary, for accumulation of aqueous humour to reveal any lenticular substance which may remain behind. The iris invariably gets into its place; if not, I set it by gentle manipulation or by allowing the rays of light to act upon it. Sometimes it may be that I have to take the aid of the curette to adjust the section and to replace the iris. I then drop in a four grain solution of atropine to put the iris at rest, and apply a pad and bandage to both eyes. I perform iridectomy, if the pupil has not responded sufficiently to atropine, or if the lens is hard and large, or if there is adhesion of the pupil, where the lens requires to be removed by a vectis or a curette, or if by accident the iris be injured, and when the patient is incapable of enduring the quiet indispensable to the prevention of prolapse of the iris. Concerning loss of vitreous in cataract operations, this accident was held for many years by operators in Great Britain and on the Continent as a calamity involving insecurity to ataversion in cataract operations. It is a remarkable fact that Mr. Charles Macnamara held and taught as far back as 1868 that loss of one-fourth of the vitreous was no bar to a perfect recovery of sight. His declaration on this matter was stoutly contested in London, but time has proved that Macnamara was right, and now our friends in Europe are reconciled to his views."

[Statistics followed with regard to loss of vitreous, showing that even when more than one quarter of this humour escaped the percentage of success was 77.]

"There is a remarkable augmentation of cures in recent times, due probably to a more extended knowledge, the selection of operations, and to antiseptics. But there is a regrettable drawback that every ophthalmic surgeon in Bengal has to contend with—that is, the need of a practical surgical instrument maker to sharpen cataract knives, as all instruments have to be sent to England for repair. Reverting to the subject of augmented success in cataract operations, the recent experiences of the Calcutta Medical College Hospital, in which, undoubtedly, individuality as a feature conducing to success has played an important part together with modern antiseptics, we find the report of the Eye Hospital of Calcutta with a percentage of cures that has reached the high figure of 95.56 per cent., but 76.13 has been the average for the past six years. Surely, this is an achievement which reflects considerable credit on Professor R. C. Sanders, our present ophthalmic surgeon. In recent times the prevalence of diabetes in Bengal has added largely to the occurrence of cataract, and it is remarkable that these patients derive considerable benefit from a judiciously performed cataract operation. The latter stages of diabetes, which usually terminate in nephritic changes, afford abundant evidence of the great value of the ophthalmoscope as a diagnostic agent of nephritic retinitis. Bengal is the land of mendicants. It is no exaggeration to say that a million

or more of the people of this rich and fertile province are beggars. This fact is of enormous significance and interest when it is found that over sixty per cent. of these helplessly poor fellow creatures are totally blind, and, further, that over 40 per cent. of these visionless objects owe their destruction to ophthalmia neonatorum. Total disregard of the simplest hygienic laws in the lying-in room, the absolutely careless neglect of cleanliness of the infant immediately after its birth, are ruefully responsible for more than half the blindness one sees in Bengal. Household therapeutics limits the treatment of sore eyes in infants to penicilling the eyelids with black sulphide of antimony or with butter and lamp-black (*kajul*), or washing them with milk and warm water, or *neem* infusion; and these ablutions are so faultily done as to allow the lids to ensack quantities of purulent matter, and thus the destructive and corrosive changes of the corneal structures go on till vision is hopelessly ruined. If only our *dhais*, or native midwives, could be trained sufficiently to regard the vaginal discharges as peculiarly prone to infect the eyes of their infant charges, how much the number of Indian mendicants could be reduced and how much of happiness could be added to the blighted lives of our fellow-creatures. For the treatment of ophthalmia neonatorum I have found the early application of a 2 per cent. solution of nitrate of silver as eye drops most beneficial. Of course, it is an eminently preventable disease, and if sufficient cleanliness be observed in washing out the vagina before birth, and in seeing to the eyes immediately after birth, it can with certainty be shorn of its ill-effects. As soon as the head of the child is born both eyes should be wiped with cotton wool before they are opened to prevent infection by any discharge that may be present, and the nurse should be instructed, when washing the child for the first time, to use different water for the eyes with a pledget of cotton wool. When this has been done one drop of a 2 per cent. solution of nitrate of silver should be dropped inside each of the eyes. Of course, while cleanliness is absolutely necessary in every case, it is only essential to guard the eyes of the infant by nitrate of silver solution as a collyrium in those cases in which there is a suspicion of impure vaginal discharges. Frequent cleansing of the eyes is a *sine qua non* of treatment, and while antiseptic solutions of such reagents as boracic acid, perchloride of mercury, permanganate of potash, &c., play a helpful part as aids, the destruction of the morbid germs, which created the disease, is most effectually performed by nitrate of silver. Granular conjunctivitis is a very common affection among the poor, consisting, as it does, of the formation of granular tracheomatous bodies in the conjunctival connective tissue. I have found it extremely prevalent in Bengal. It is undoubtedly due to malhygienic conditions of life. Among the various forms of treatment I have found nothing to equal dusting the lids with tannic acid both morning and evening, then once a day, and later on every other day. In the meantime keep the eyes scrupulously clean by the frequent application of antiseptic drops, such as boracic acid and perchloride of mercury. Tannic acid sets up sufficient inflammatory changes to cause absorption of the neoplastic bodies. Sulphate of copper was much used in former days. We still apply the *lapis divinus* to granular lids. But I think tannic acid can better reliably take its place. The various reputed specifics of a decade ago, such as acetate of lead, quinine dusting, solution of perchloride of mercury, and strong solution of nitrate of silver, have all had their day; but sanitary measures, generally tonics, and tannic acid dusting, hold the highest place in affording relief and cure to this troublesome and painful disorder. Glaucoma is another commonly prevalent disorder in Bengal. Iridectomy is the sheet-anchor of cure of this most dreadful affection. In Bengal much difficulty is experienced in inducing sufferers from glaucoma to undergo the necessary surgical operation of iridectomy, and so recourse has long been had to various other forms of relieving intra-ocular tension by means of leeching and by ordinary antiphlogistics; but more recently the discovery of the great therapeutic value of eserine has placed in the hands of Indian practitioners a most accommodating and efficient aid. The use of eserine affords relief for some time, and by-and-by the patient makes up his mind for an iridectomy. In many cases a fair field of vision is maintained by the use of eserine, while the further progress of the disease is cut short. In atrophy of the disc (a common ailment) the use of eserine collyria and the subcutaneous injections of atropine have afforded the best results. It is remarkable how prevalent this disorder is among excessive tobacco

smokers and in those who use ganja and alcohol. The rigorous enactments of the Bengal Education Code, and the high mental tension which arises out of the keen competition that marks the training and education of our youths of to-day, have resulted in a most deplorable augmentation of the errors of refraction and accommodation; and so we find boys and girls of twelve to sixteen years decorated with spectacles—a sight that would horrify our forefathers were they to return to their mundane sphere."

[In concluding his paper Professor Mukherji earnestly appealed for a more systematic and thorough training of students in Indian colleges in eye diseases, and paid a warm tribute of gratitude to England for the part she had taken in advancing Indian medical science.]

Medical News.

DR. WILLIAM SLIMON of Bow, E., has been placed by the Lord Chancellor upon the Commission of the Peace for the County of London.

FOOTBALL CASUALTIES.—During a recent match between the Notts County and Grimsby Town teams a player fractured his clavicle.—At Tipton, Staffs, a young man while playing a match sustained "internal injury," from which he died last week.

ON Friday, Jan. 25th, the governors of the Royal Victoria Hospital, Bournemouth, held their annual meeting in the Havergal Hall, the Earl of Malmesbury presiding. According to the report 4225 cases had been treated during the year, exceeding by 566 the number under treatment in 1893. The expenditure for the year had exceeded the income by £184 15s. 10d.

THE seventh annual meeting of the Brighton, Hove, and Preston Dental Hospital was held on Wednesday, Jan. 30th, at the institution, Alderman Dr. J. Ewart presiding. During the past year the admissions to the hospital had been 2993, anaesthetics being used in 324 cases. The chairman remarked that the hospital was still in a very flourishing condition, but regret was expressed at the small number of donations received from workmen's boxes, seeing that 50 per cent. of the patients were either workmen or members of workmen's families.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Goldscheider, Kroenig, Immanuel Munk, and Leopold Landau have been granted the title of Professor.—*Kazan:* Dr. Kotovshchikoff has been promoted to the Professorship of Clinical Therapeutics, in succession to the late Dr. Khomiakoff. Dr. Kazem-Beck has been appointed Extraordinary Professor of Medical Diagnosis.—*Kharkoff:* Dr. Anfimoff of Tomsk has been appointed to the chair of Neurology and Mental Diseases. Dr. Orshanski has been promoted to an Extraordinary Professorship of the same subjects.—*Paris:* Dr. G. Filomusi-Guelfi has been promoted to the Ordinary Professorship of Forensic Medicine. Dr. Fasola has been recognized as *privat-docent* in Experimental Physiology.

OBSTETRICAL SOCIETY OF LONDON.—The annual general meeting of the Obstetrical Society of London was held on Wednesday last, when the principal business was the election of officers for the ensuing year. The proceedings on these occasions are generally of a formal character, the list recommended by the council being usually adopted *ex bloc*. This time, however, we are informed many Fellows of the Society were dissatisfied at not finding Dr. Cullingworth among those recommended for high office by the council, and it was known that at the meeting on Wednesday they would endeavour to give effect to their views. The result was that in a full meeting the list recommended by the council was adopted, with the exception that Dr. Cullingworth was elected to the post of Chairman of the Board for the Examination of Midwives. We append the complete list:—President: Francis Henry Champneys, M.A., M.D. Vice-Presidents: James Duncan, M.B., John H. Galton, M.D., Peter Horrocks, M.D., and Thomas Cargill Nesham, M.D. (Newcastle-on-Tyne). Treasurer: John Baptiste Potter, M.D. Chairman of the Board for the Examination of Midwives: O. J. Cullingworth, M.D. Hon. Secretaries: William Duncan, M.D., and W. Radford Dakin, M.D. Hon. Librarian: John Phillips, M.A., M.D.

WE learn with regret of the sudden death of Mr. Burroughs, of the firm of Messrs. Burroughs, Wellcome, and Co., from pneumonia, at Monte Carlo, on Wednesday last.

THE yearly meeting of the Harrogate Royal Bath Hospital and Rawson Convalescent Home was held at the hospital on Jan. 24th. The sixty-ninth annual report was presented and showed that upwards of 1000 patients had received benefit during the eight months in which the hospital and home were open for their reception. Of these patients 831 were treated in the Royal Bath Hospital, including cases of eczema, psoriasis, gout, rheumatism, and hepatic disease. Two deaths occurred—one from rupture of a bloodvessel and the other from cancer of the liver. The sulphur baths numbered 6457. Two hundred and two cases were treated in the Rawson Convalescent Home.

THE annual meeting of the Jenny Lind Infirmary for Sick Children was held on Jan. 30th at the Infirmary, Pottergate-street, Norwich, the Mayor of Norwich (Colonel Bignold) presiding. An influential company assembled, including the High Sheriff of Norfolk (Mr. J. H. Gurney), the Deputy Mayor (Sir Peter Eade, M.D.) and Lady Eade, Sir Frederic Bateman, M.D., and the Dean of Norwich (Dr. Lefroy). The report showed that the total number of patients last year was 1333, of whom 198 were in-patients. The financial position was satisfactory, the income having been £430 in excess of the expenditure. A medallion bust of the late Madame Jenny Lind was presented to the institution by Mr. Goldschmidt.

THE METROPOLITAN HOSPITAL SUNDAY FUND.—The Right Hon. the Lord Mayor, Sir Joseph Rennals, Bart., presided at a meeting of the Council of the Metropolitan Hospital Sunday Fund on Thursday last, when the following committees were nominated and re-elected:—Committee of Distribution: Sir Savile Crossley, Bart., Sir David Evans, K.C.M.G., Mr. H. Cosmo O. Bonsor, M.P., Captain James Cundy, Mr. Herman Hoskier, Mr. F. H. Norman, Dr. W. Sedgwick Saunders, and Mr. Alfred Willett, F.R.C.S. General Purposes Committee: The Chief Rabbi, the Ven. Archdeacon Sinclair, the Rev. Canon Fleming, the Rev. Canon Ingram, the Rev. Donald McLeod, the Rev. J. Kennedy, the Rev. J. H. Rigg, the Rev. Dr. Marks, the Rev. W. H. Harwood, the Rev. J. F. Kitto, M.A., the Right Hon. Lord Sandhurst, Colonel Francis Haygarth, Mr. Herbert Brooks, Mr. Henry C. Burdett, Mr. F. C. Carr-Gomm, Mr. A. L. Cohen, Dr. J. G. Glover, Dr. C. J. Hare, Mr. Albert G. Sandeman, Dr. W. Sedgwick Saunders, and Mr. Wakley, F.R.C.S. Sir Edmund Hay Currie and Mr. Richard B. Martin, M.P., the honorary secretaries, were re-elected, as was also Mr. H. N. Custance, the secretary to the Fund. Messrs. W. H. Pannell and Co. were appointed auditors for the ensuing year, and the usual courtesies to the Lord Mayor as chairman terminated the proceedings.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

THE fourth session of the twenty-fifth Parliament of the United Kingdom opened on Tuesday, Feb. 5th.

Alterations in the House of Commons.

During the recess extensive and important alterations and improvements have been made in the House of Commons and the buildings adjoining. They are in most part based on recommendations adopted by a Select Committee which sat last session, although they do not follow these recommendations rigidly. Very little has been done in the legislative chamber itself. Some alteration has been made in the arrangements for strangers, and in the Press Gallery the old door has been taken away and two new ones substituted, a change which, it is hoped, will add materially to the convenience of those who use this part of the House. For a long time the heating and ventilation of the chamber have been subjects of complaint by members, but on the present occasion nothing has been done in this connexion. A further report, however, has been made by Mr. James Keith, in which serious defects are pointed out and several suggestions put forward. With this report before them, the authorities of the House should at least be able to do something to improve matters. In the buildings adjoining the legislative chamber several very substantial changes have been made. For instance, the kitchen where the meals of members are cooked has been enlarged and its apparatus supplemented. A magnificent grill has been fitted up. In another part of the building four commodious bath-rooms have been provided, and in their neighbourhood

a hair-dressing room, where members will be able to have a shampoo and "make their toilet." Then there is a new dressing-room with six curtained cubicles, and the servants, who are a very large body and who hitherto have had no special accommodation allotted them for their meals, have been provided with a very adequate Servants' Hall. Considerable addition has also been made to the smoking-room accommodation for members of the House and the Press Gallery. The whole work has cost between £14,000 and £15,000.

Old Age Pensions.

Mr. Henry Broadhurst has given notice that he will seek a date for the discussion of the following motion: "That in the opinion of this House all persons of sixty years of age and upwards shall be entitled to a pension on application to the local authority of the district in which the applicant is resident."

Food and Drugs Adulteration.

Steps will be taken as soon as possible to appoint a select committee to resume the inquiry started late last session into this subject. Endeavour will, of course, be made to enlist the services of the members who served on last year's committee.

The Opium Commission.

Mr. Bartley has given notice that he will ask the House to express the opinion that no part of the cost of the Royal Commission on Opium should be defrayed by the natives of India.

HOUSE OF COMMONS.

THURSDAY, FEB. 7TH.

Electric Light Accidents.

Mr. Howart questioned the President of the Board of Trade with reference to recent electric light accidents in London, and Mr. Bryce, in the course of his reply, said that the Board of Trade was earnestly pressing upon the electric lighting companies the necessity of taking proper precautions to prevent accidents.

Tuberculosis Commission.

In reply to a number of questions, Mr. Shaw-Lefevre said the Government greatly regretted the delay that had occurred in connexion with the inquiry of this Commission. During the recess he had been in communication with the chairman on the subject, and he fully realised how much importance was attached to the early publication of the report. When the Commission met at the end of the present month or the beginning of March, a draft report would be before them for their consideration.

The Consolidation of the Poor-laws.

Mr. Shaw-Lefevre, replying to Mr. Howell, said he was afraid the engagements of the Government would quite prevent their introducing a Bill to consolidate the Poor-laws during the present session.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

BANCROFT, PETER, M.B., Ch.M. Syd., has been appointed City Health Officer of Brisbane, Queensland.
BARNETT, L. E., M.B., C.M. Edin., F.R.C.S. Eng., has been appointed Lecturer on Surgery to the Otago University Medical School, Dunedin, New Zealand, vice Wm. Brown.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

THE INDEX TO THE LANCET.

THE Index for the last half-year was published in our issue of Dec. 29th, which completed the second volume of the year 1894. Those of our subscribers who may wish to be supplied with loose copies can obtain the same (without extra charge) on making application to the Manager.

"DETERIORATION OF CORKS."

WE have received several letters from medical men the gist of which is that our previous correspondent on this subject is badly served, and that corks as good as the corks of old are still in the market.

"ON THE TREATMENT OF GLEET BY THE URETHROSCOPE.
To the Editors of THE LANCET.

SIR,—My attention has been called to a letter under the above heading in your issue of Jan. 12th. I have hesitated making an explanation, as the letter, like most others of its class, bears an anonymous signature. The copy of the Medical Week which "M.D." objects to was sent to me by the author of the article in question, who

is a personal friend of mine. I am entirely to blame for its appearance in the Isthmian Club, where I left it accidentally. The blue pencilling was for my benefit. I should have thought that the name which headed the article, bearing as it did the letters "F.R.C.S.," would have been sufficient to have protected its author against the suggestion of advertisement amongst members of a club "which are chiefly young men." "M.D." would have shown more discretion and good taste if he had placed his grievance in the hands of the secretary of the Isthmian Club, who is thoroughly well able to protect its interests.

I am, Sirs, yours faithfully,
Isthmian Club, Piccadilly, W., Feb. 1st, 1895. STANLEY DAVIES.

THE EXHIBITION OF HYPNOTISED SUBJECTS.

To the Editors of THE LANCET.

SIRS.—On Friday the 1st inst. I attended with others as a spectator to witness a hypnotic *séance* at the Royal Aquarium. The two medical men who had agreed to watch the proceedings being absent in consequence of a postponement of the time, Mr. Ritchie, the chairman of the board of directors, seeing me in the room, asked me to examine the man, who was lying in a sort of coffin. I found a fairish strong man to all outward appearances, the pulse weak but regular, and large dilated pupils. In about one minute and a half Mr. Morrill placed him in a complete trance. The pulse then got much stronger, from 75 to 95, whilst the pupils of the eyes became much contracted, the breathing becoming purely abdominal. The *séance* commenced at 7.30 P.M. He continued quite unconscious throughout; but on Saturday at 11 P.M., in consequence of a threatened failure of his heart, the beating of which was scarcely perceptible, whilst the temperature had gone down from 97.2° F., which it was in the morning, to 96.4°, together with a cyanotic condition of the face, induced Dr. Trevor, who was in attendance, and myself to consider that a continuance of the proceedings with that subject was an unwise one. He was at once brought to consciousness, and our opinion was justified by finding that he had a weak, dilated heart and swelling in the ankles. The original man on whom this experiment was to be tried failing to appear at the last moment, Nolan was put in his place without any sort of preparation as regards diet. He is none the worse beyond feeling very thirsty and a tingling in the feet. His insensibility was absolute throughout the thirty hours.

I am, Sirs, your obedient servant,
Devonshire-street, Feb. 5th, 1895. FORBES WINSLOW.

To the Editors of THE LANCET.

SIRS.—Will you kindly allow me space to protest most strongly against the patronage and co-operation of medical practitioners in the placing of a man under hypnotic unconsciousness as a show at the Royal Aquarium? In some other countries such a public exhibition would have been unlawful, and I had hoped that even the medical advocates of hypnotism would have condemned such a performance in a place of public resort and amusement.

I am, Sirs, yours obediently,
Grove-road, N.W., Feb. 5th, 1895. NORMAN KERR, M.D.

CORK SOCIETIES' MEDICAL OFFICERS' INDEMNITY FUND.

D. D. DONOVAN, Hon. Treasurer.

M. B.—Our correspondent's is a very legitimate complaint, and we hope to be able to refer to it more fully at an early opportunity.

Dr. J. B. Helliier.—The communication is marked for early insertion.
Enquirer.—Yes.

A QUERY.

To the Editors of THE LANCET.

SIRS.—Can any of your readers inform me of a suitable home or school at reasonable terms for a boy of about fourteen who is deficient in intellect? So far as I have been able to ascertain there is no choice between giving £70 or £80 per annum and the parish schools at Darenth. My patient might be able to afford £35 to £40 per annum, but not more.

I am, Sirs, yours faithfully,
Feb. 6th, 1895. J. P. S.

WANTED, HISTOLOGICAL SLIDES.

To the Editors of THE LANCET.

SIRS.—I shall be very much obliged if any of your readers can tell me where I can obtain histological slides (preparations) ready put up for the microscope, as I have not time to prepare them myself and my own old school ones have more or less gone wrong?—Yours faithfully,
Jan. 30th, 1895. MEMBER.

QUALIFIED DISPENSERS.

To the Editors of THE LANCET.

SIRS.—Be pleased to inform me as to any other bodies besides the Apothecaries' Hall who grant certificates qualifying dispensers.

I am, Sirs, yours faithfully,
Feb. 1st, 1895. CHEMIST.

* The Pharmaceutical Society grants certificates to dispensing chemists to act as such. This is the only legal qualification in England and Scotland.—ED. L.

RICHARDSON'S MEDICAL ASSISTANTS' AGREEMENT FOR SERVICES.

THIS is a form of agreement which principals may find useful in engaging assistants. It is very explicit. It can be obtained from Messrs. Richardson Bros. and Co., Medical Agents, Liverpool.

A Twenty Years' Subscriber.—Certainly so. He could put nothing on his plate more proper or to the point.

Dr. E. Robinson.—Our correspondent's course appears to us to have been perfectly correct

BACTERIA IN BREAD.

To the Editors of THE LANCET.

SIRS.—Please allow an American physician (now travelling in Europe) to state in your columns that attention was called to the subject of bacteria in bread as early as 1832 in a paper read before the Philosophical Society of Great Britain upon the relations of "Yeast to Man." This paper was written upon invitation and forwarded to the society by Dr. Ephraim Cutter, now of New York, a graduate of the Harvard University Medical School, in 1856. It was profusely illustrated by most excellent micro-photographs and drawings executed by an American artist, and displayed bacteria in common bread, pilot bread, and pumper-nockel, the latter being richest of all in bacteria. As this subject has been recently revived by communications to medical societies and articles in THE LANCET and other journals, both in England and America, it would seem an act of justice to acknowledge the work of a pioneer in this important department.

Gibraltar, Jan. 12th, 1895. YOURS TRULY, CLASSMATE.

THE QUALIFIED ASSISTANT AND THE FEES FOR NOTIFICATION.

To the Editors of THE LANCET.

SIRS.—I should like to know whether a qualified assistant is entitled to claim the fees for notifications of infectious diseases sent to the medical officer of health, or whether the principal is entitled as employer to the fees for notifications notified by his assistant.

I am, Sirs, yours truly,
Feb. 4th, 1895. INQUIRER.

* The Infectious Disease (Notification) Act knows nothing of principals or qualified assistants. The medical practitioner "called in" to the patient is bound to send in the notification certificate, whether he is the principal or the assistant, and the local authority is bound to pay the fee to the medical practitioner "for each certificate duly sent by him." The qualified assistant in notifying infectious disease, as in all his other duties, is acting for his principal. Apart from some special arrangement he is not entitled to the notification fees.—ED. L.

"WANTED, A LANTERN AND SLIDES."

To the Editors of THE LANCET.

SIRS.—"Subscriber" would find what he wants in the way of physiological lantern slides of a popular character in a series called "The Human Body, or the House I Live In," by Furneaux, to be obtained of any optician dealing in lantern slides, from whom he could also obtain lanterns on hire.

I am, Sirs, yours truly,
Richmond Hill, Feb. 5th, 1895. G. E. SHUTTLEWORTH.

To the Editors of THE LANCET.

SIRS.—"Subscriber" will get all he requires, and of the very best, at Messrs. Newton and Co., 3, Fleet-street, Temple Bar, E.C. Sets of slides copied from physiological works may be obtained also from many places, as Mr. Luscombe Toms, 78, Queen Victoria-street, E.C.; Mr. Walter Tyler, 48, Waterloo Bridge-road, S.E., and others, from whom also lanterns and fittings can be hired.—I am, Sirs, yours faithfully,
Feb. 4th, 1895. J. G.

INSURANCE AND CARDIAC MURMURS.

To the Editors of THE LANCET.

SIRS.—Is there any circumstance in which a medical examiner for insurance would be justified in recommending an insurance company to accept a person suffering from a cardiac murmur?—Yours truly,
Feb. 4th, 1895. BAYNEHAM.

Mr William Horne.—We never recommend practitioners, treatment, or particular hospitals.

Mr. A. Thornhill Greenhill.—The post alluded to is not vacant.

Dr. W. Sumpter is thanked for his communication.

ERRATUM.—In a review of the "Indian Manual of Hygiene," published in our issue of the 12th ult., we omitted to mention that the London agents for the book are Messrs. H. K. Lewis of Gower-street.

During the week marked copies of the following newspapers have been received:—Midland Herald, Sevenoaks Chronicle, Arbroath Guide, Dundee Advertiser, South Wales Argus, Milton Sunday Chronicle, Warwick Gazette, Sussex Daily News, Midland Evening News, Birmingham Post, Jewish World, Truth, Walsall Observer, Umpire, Australasian Medical Gazette, Bristol Mercury, Times of India, Folkestone Express, Isle of Man Times, Limerick Chronicle, Manchester Guardian, Bedfordshire Times, East Morning News, Family Doctor, Hereford Times, Kensington Society, Loughborough Examiner, Glasgow Evening Times, Scotsman, Banffshire Journal, Elgin Courier, Montgomery County Times, Public Health, Kenish Express, Sunday Times, Ayr Advertiser, Express and Star, Citizen, Warwick Times, Essex Telegraph, Kenish Press, Manchester Evening News, Western Daily Mercury, Wallacey Chronicle, &c., &c.

Communications, Letters &c. have been received from—

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to fictitious names or initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials &c. sent to the Office in reply to advertisements; copies only should be forwarded.

Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

An Address

ON

APPENDICITIS.

Delivered before the Surgical Section of the College of Physicians of Philadelphia,

By J. WILLIAM WHITE, M.D.,

PROFESSOR OF CLINICAL SURGERY AT THE UNIVERSITY OF PHILADELPHIA.

GENTLEMEN,—It has been my intention in preparing this paper merely to review some of those important points relating to the cause, course, and diagnosis of appendicitis, and more especially to its treatment, about which great differences of opinion still exist in the profession, and to make my own slight contribution towards the acquirement of a fulness and certainty of knowledge which will permit us at some future day to lay down certain broad general propositions accepted and endorsed by both surgeons and physicians.

As regard etiology, we may first consider (a) the predisposing causes. The explanation of the great frequency with which the appendix becomes the seat of inflammatory and destructive lesions as compared with the other portions of the digestive tract is undoubtedly to be found in its anatomical relations. There can be no question that those structures which remain to us as functionless vestiges of parts once useful are possessed of low vitality and but feeble resistant powers. In addition, its dependent position, its communication by an orifice, often more or less narrowed, with that portion of the intestine in which inspissation of intestinal contents first occurs, while at the same time it is removed from the direct fecal current, all appear to be conditions so markedly predisposing to inflammatory attacks that we need look no further for a sufficient explanation of the extraordinary frequency of appendix trouble. We may next consider (b) exciting causes. Putting aside the comparatively rare cases in which tuberculous or other general disease localises itself in the appendix, we have two chief classes of exciting agencies, clinical differentiation of which is to be earnestly aimed at: the mechanical, and the bacterial or infective. The latter comes into play usually, perhaps almost constantly, as a sequel of the former, which may, I believe, exert its action alone from first to last in many cases. The following anatomical points must be remembered. The appendix is commonly found curved upon itself because its mesentery, derived from the inferior layer of the mesentery of the ileum, is too short for it. Along the free concave border of the mesentery runs a single vessel, a branch of the ileo-colic, and from this branch the appendix as a rule derives almost its entire blood supply. Another peritoneal fold runs from that part of the ileum most remote from its mesenteric attachment and is united with the mesentery of the appendix. It carries no bloodvessels. It is the remains of the true mesentery of the appendix. (Treves.) It is interesting to note the fact that in the different types of cæcum found in our species those which involve a disproportionate growth of the cæcum show that it derives its peritoneal covering partly at the expense of the mesentery of the appendix, which becomes more and more scanty and more vertical in direction the larger the relative size of the cæcum. We here have the factors which enter into the production of a large number of cases of appendicitis. Distension of the ileum with gas or of the caecum with gas or fecal matter will cause dragging on one or the other of these folds, already too scanty, increase the torsion of the appendix, interfere with the blood-supply through its single vessel, and according to the degree of torsion produce congestion and tumefaction, catarrhal inflammation, ulceration or gangrene, with the clinical symptoms that belong to each. The importance of the matter will be apparent if we remember that it has been asserted that all cases of appendicitis are infections in their nature, and that from this assumption has followed the corollary that all cases should be operated on, as one attack means almost certainly another at some future time. It seems probable, though hardly yet proven, that the bacterial cause of appendicitis is as a rule the

No. 3729.

bacterium coli commune. It is almost invariably to be found in the intestinal tract, and seems in the presence of sound mucous membrane to have little or no power for evil. But it is equally well demonstrated that if the epithelium is once destroyed it has both pathological and pyogenic properties. (c) A third class of causes which may be regarded as both predisposing and exciting must be made to include fecal concretions and foreign bodies. The latter, once thought to be the chief factors in producing the disease, are now known to be of great rarity, occurring in only about 4 per cent. of operative cases.¹ Fecal concretions are found in 15 to 20 per cent. of such cases, and there is evidence to show that they may occasionally by their presence give rise to the lesion of the mucous coat which precedes infective processes, but they are so often absent in cases of all grades of severity and so often present at necropsies on persons who have died from other diseases that they should not be considered of primary importance.

How are we to recognise clinically the cases in which the mechanical element alone is the factor and the circulatory disturbance stops short of the production of necrotic lesions of epithelium, mucous membrane, or appendix wall? If the views advanced as to etiology are sound, not only do such cases occur but they probably outnumber the more serious forms of the disease, frequent as are the latter. Statistics support this view, as there is good reason to believe that from 60 to 80 per cent. of cases of appendicitis recover without operation, and in the majority of these cases an infectious element must almost certainly be absent. Nor do the facts bear out the assertion so often made recently that such recoveries are merely apparent or temporary. If we review the early symptoms of a typical case of so-called mild or catarrhal appendicitis and assign each to its anatomical or pathological cause it is discouraging to find that thus far we have at this stage practically no means of distinguishing the cases which are going to stop short of grave organic lesion from those which, unless cut short by surgery, are predestined to almost certain fatality. Let us suppose that we have a case in which constipation (which has been obviously or unsuspectedly present in 90 per cent. of my cases) or diarrhoea, or at least some digestive derangement, has caused intestinal distension with fecal matter, or with gas, or irregular and excessive peristalsis in the ileo-cæcal region. The meso-appendix is dragged upon, the torsion of the appendix increased, and the return of blood interfered with; the arterial supply, more difficult to disturb than the venous current, is but little affected. If we could see such an appendix we would undoubtedly find swelling and congestion, hypersecretion, and nerve irritation. It seems to me theoretically unreasonable to suppose that in every such case there is necrosis even of epithelium or infection even of low grade. The usual symptoms of such a case as we are considering, with their explanation, are: Pain, at first general and diffused over the abdomen, because the superior mesenteric plexus of the sympathetic, which supplies the appendix, also largely supplies the intestines, and because irritative nerve pain is apt to be referred to the peripheral extremities of nerves; next, and within a very short time, it is felt in the umbilical region, because as such pain increases in intensity it is often referred to the nearest nerve centre, and the great sympathetic ganglia of the abdomen are situated in that region. After a few hours there is tenderness on pressure in the right iliac fossa. It is a localised tenderness in all the varieties of appendicitis, because, while the appendix itself is movable, it always arises from the same part of the cæcum, and the mobility of the latter is much more restricted. The point of pain on pressure known as McBurney's point indicates, therefore, with moderate accuracy the base, not the tip, of the appendix, and is rarely absent even in gangrenous cases, because that portion of the appendix is usually the last to be affected by interference with the blood-supply. Vomiting commonly follows, has little relation to gastric conditions, and is ordinarily reflex and due to reversed peristalsis as the ejecta show a degree of digestive change corresponding to the time which has elapsed since the last meal. Moderate fever (99.5° to 101° F.) and slightly increased pulse-rate (90 to 110) are usually present, and are doubtless due to the absorption of intestinal products. There is slight rigidity of the right rectus muscle, and later of the other abdominal muscles over the right iliac fossa, often, but perhaps not necessarily, due to peritonitis, and in any event arising from

¹ Matterstock, Fowler.

the fact that those muscles receive their nerve-supply from the seven lower intercostals, while the superior mesenteric plexus gets its contribution from the spinal system through the splanchnics derived from the same seven intercostals.

This group of symptoms includes all that are of any value in this type of appendix trouble. It has been asserted (Rushmore, Osler, and others) that to speak of the first day that the patient complains of pain as the first day of the disease is fallacious, and it is said that what we recognise in appendicitis is peritonitis, which has been preceded by ulceration of the mucous membrane and a perforation of the appendix itself. Now, if this were demonstrably true it would, I think, oblige us to accept the rule laid down by some surgeons that the diagnosis of appendicitis brings with it the obligation to operate. But it is demonstrably untrue. Not only does not every case with the above symptoms have precedent ulceration, but there have now been enough early operations and removals of appendices at this stage to enable us to say positively that, apart from the conditions already described—swelling, congestion and associated vascular changes, and nerve irritation—there are often no grave lesions of either the mucosa, the parietes of the appendix, or of its peritoneal covering. While the explanation already given of the etiology and symptoms in these cases shows (1) that they may depend upon mechanical causes and are not necessarily infective, and (2) that there is no phenomenon associated with them which of itself indicates either a solution of continuity of the mucosa, infection of the appendix wall, or peritonitis, unfortunately it must also be said that there is none which excludes the graver conditions. Colicky pain, localised tenderness, slight abdominal rigidity, vomiting, and moderate fever may be the only symptoms of a case which is going on to a rapid termination by gangrene, perforation, and septic peritonitis. It must therefore be decided whether, taking a large number of such cases, medical treatment or operation offers the best chance for recovery. At present the facts seem to be as follows. Perhaps 80 per cent. of cases of this type recover under medical treatment. Of the remaining 20 per cent. at least one half can be saved by operation during the condition of localised abscess which would form in probably that proportion of cases. Of the remaining ten, in which no protective adhesions would form, a certain indeterminate proportion would recover after operation done before septic peritonitis and intestinal paralysis had occurred. This would leave a death rate of, say, from 5 to 8 per cent. If, on the other hand, every case were operated on as soon as seen, would this death-rate be increased or diminished? The operation, however skilfully conducted, means of necessity a certain amount of traumatism to the peritoneum, and an equivalent diminution of its local resistant power. Most surgeons of experience will agree with Treves, who in his recent admirable Lettsomian Lectures says: "There is no doubt that the nervous disturbance which attends any abdominal operation leads to some degree of intestinal paralysis. This paralysis, attended as it is by vaso-motor changes in the bowel wall, is favourable to the absorption of septic matters from the intestine." It should also be remembered that Terillon has shown that the effect of irritation of the parietal peritoneum, which is chiefly disturbed in ordinary exploratory operations, is comparatively feeble, while it is violent and intense when that covering the intestines is involved. (Treves.) Therefore, while both my experience and my observation lead me to believe that in good hands these very early operations will have an extremely low mortality, perhaps lower than that of the disease treated medically, I do not believe that it will be "practically nil."

As to the diagnosis of the class of cases we have just been considering, it is to be made chiefly from stercoral typhilitis, a condition which has been so overshadowed during the advance of our knowledge in regard to appendix disease that we are in danger of acting as if it were non-existent. It has many features in common with appendicitis, and it is quite possible, as has been asserted, that to some degree this is present in most cases of stercoral typhilitis; but the independent existence of the latter condition has been shown unquestionably, both at necropsies and at operations where severe forms of typhilitis and perityphilitis have been found, to be dependent on stercoral ulcers of the cæcum, the appendices being normal. The relation of the mild attacks of appendicitis to digestive derangement has been quite unmistakable in my experience, and it is not very uncommon to find in relapsing appendicitis that one particular article of food is

the especial exciting cause of an attack. Now, if in so many cases fecal distension of the cæcum is the starting point of appendicitis, it is reasonable to believe that in some of them the trouble does not pass beyond the cæcum, and it is important to recognise these cases because the prognosis is so much more favourable and operative measures need not, as a rule, be thought of. They have occurred with me chiefly at the times of life when appendicitis is less common, and more especially in children. They can be recognised with certainty only by the initial presence of a doughy, sausage-shaped tumour in the cæcal region, associated with the usual symptoms of appendicitis in a modified form. The localised tenderness is not so great, the fever is very moderate, vomiting is rarely a prominent symptom, and constipation is almost invariable, though occasionally a spurious diarrhoea may make its appearance. The discovery of a tumour in the very beginning of an attack of apparent appendicitis of obviously mild type would, I think, justify the diagnosis of stercoral typhilitis; but I know no other way in which the diagnosis can be made, and in the absence of that symptom it would be safer to consider doubtful conditions as almost certainly indicating appendicitis.

CASE 1.—A little girl had an attack of vomiting followed by umbilical pain and almost immediately by right iliac tenderness. When first I saw her, about eight hours after the beginning of the illness, a distinct mass could be felt in the cæcal region; tenderness at the edge of the right rectus in the omphalo-spinous line was marked; she lay on her back, with the knees drawn up. Her temperature was 101° F. and her pulse 110. Her mother stated positively that the bowels had acted regularly and that she had never known her to be constipated. Salines which had already been given were continued. Hot fomentations were applied to the abdomen. The diet was reduced to teaspoonful doses of peptonised milk at hourly intervals. At the end of twenty-four hours there was a little aggravation of all the symptoms; at the end of forty-eight hours there was slight tympany; at the end of sixty hours, when we were considering the advisability of operation, there was an enormous stool, followed by two others in rapid succession and by a complete disappearance of all the symptoms.

It will be convenient now to consider the non-operative treatment of these mild "catarrhal" cases before passing to those of the next grade. Ordinary clinical experience with other forms of enteritis demonstrates the value of absolute rest in bed and on the back. The frequent inability of the stomach to retain food, the certain inability of a portion of the intestinal tract to take care of the residue even if it reaches that point, and the absolute need for the avoidance of all sources of local irritation point clearly to a diet reduced to the lowest possible terms. The use of heat, drawing the blood to the superficial veins of the abdomen, of cold, by means of ice kept on long enough to bring about local anæmia extending to the parietal peritoneum or deeper, and the actual abstraction of blood by leeches seem to have about equal claims to employment. Personally I prefer either the heat or the blood-letting. I strongly object to blisters, iodine, and ointments as rendering the skin unsuitable for a satisfactory operation later if one be required. The question about which there is the widest apparent divergence of opinion concerns the respective merits of the use of salines and the use of opium. My present opinions, which have not been reached without some thought and much hesitation, but which seem to me more and more satisfactory as my experience widens, are based on the following considerations. I have never happened to see one of these extremely mild cases, in which there was diarrhoea, or one in which the bowels were moved easily by enemata or aperients, run into the graver type of case. Every surgeon who has had any abdominal work knows how essential it is to have the intestinal tract thoroughly evacuated before operation. It is in this way and by the prompt administration of salines according to Tait's plan on the first appearance of symptoms of "pseudo-ileus" that general peritonitis is often avoided, not cured as is incorrectly stated. As any cause of appendicitis may become an operative case it is of the highest importance that in the early stages whatever remains of peristalsis should be encouraged and not destroyed by the use of opium. For these various reasons my rule in practice is in all ordinary mild cases to give salines until free purgation is assured, and then to continue the action more gently by the use of divided doses of calomel, which by its antiseptic properties has a distinct value, and through its effect on the portal circulation aids also in the depletion of the ileo-colic vein and its tributaries.

Spontaneous severe colicky pain, altogether distinct from pressure tenderness, is the only indication I recognise for the use of opium, and I give it then in minute doses combined with enough calomel to overcome its constipating tendency. I am at present satisfied that this treatment is practically sound, and I am certainly convinced that many patients to whom opium is given early and freely die partly because the imperative need for operation is thereby disguised and the favourable opportunity lost, and partly because that free evacuation of the bowels so necessary for success is interfered with. I may say here before leaving the subject of the medicinal treatment at this early stage that, in my judgment, not enough attention has been paid to what might be called the antiseptic treatment of appendicitis. It is reasonable to suppose on *a priori* grounds that in a disease the most serious varieties of which are produced by infection with micro-organisms whose habitat is the digestive tract intestinal antiseptics would be of distinct value. And furthermore I would say that in all forms of sepsis, present or threatened, there is good reason for believing that the systematic administration of soluble and powerful antiseptics is of far more importance than is commonly supposed. If the medicinal and dietetic treatment has been successful the symptoms gradually disappear, the local tenderness often being the last to go. Scrupulous continuance of rest, restricted diet, and mild laxatives should be continued for from one to two weeks. If the symptoms are worse instead of better at the end of forty-eight hours, or earlier than that if there is severe sharp pain, increased tenderness and rigidity of the abdomen, and beginning tympany, either local or general, I think there can be no doubt that surgical interference offers by far the best hope of recovery. In the majority of cases these phenomena then indicate a perforation of the appendix wall, possibly not macroscopic, but permitting the filtration through it of bacteria and their products. So far as diagnosis goes there is practically no condition for which such a case can be mistaken. It is of course not impossible for resolution to take place in these cases. Not every one of them goes on to gangrene in mass and to infection of the general cavity. Even if resolution does not occur a protective inflammation may wall off the appendix and does so in a large proportion of cases. But there is absolutely no way of recognising with any reasonable certainty which of these three events will follow: resolution and recovery; localised abscess, with from 90 to 95 per cent. of chances in the patient's favour; or general peritonitis, with almost sure death if it is once well established. If operation is done at this stage it is unusually easy. An incision two or three inches in length is better than a smaller one, and is most advantageously placed if it is oblique, with its centre a little outside of McBurney's point. There will usually be found a moderate excess of peritoneal fluid, clear or only slightly turbid, a circumscribed peritonitis, weak adhesions between the cæcum and the parietal peritoneum and adjacent intestines, and a tense, swollen appendix. It can be removed most safely by making a circular incision through its peritoneal coat three-quarters of an inch from the base, reflecting it like a cuff, ligating the mucous coat with a circular ligature, touching its surface with a drop or two of pure carbolic acid, replacing the peritoneal coat, and stitching with a Lambert suture. When the peritoneum has become thickened and brittle almost equally good results can be obtained, and more expeditiously, by throwing a ligature around the whole appendix one quarter to half an inch from the cæcum, removing the organ and cauterising the stump with carbolic acid. As a rule the wound may be closed without drainage, and if closed properly the risk of ventral hernia is a very small one. The operation will certainly have a small mortality, but for reasons already given it will be a larger one than if it were a simple exploratory operation. While, however, I believe more patients would be saved by operation at this time than by any temporising measures, I may say that experience has taught me to await events with more equanimity: 1. If the bowels are loose. 2. If the pain is dull and throbbing (connective tissue pain, Bryant), and not sharp and lancinating (serous tissue pain); the former I refer to a tense appendix with infiltration of the wall, but without gross perforation or intense or widespread peritonitis. 3. If the spot of greatest tenderness on pressure by a finger-tip is not precisely at McBurney's point. This is an empirical rule, but I have noticed in a number of cases in which there was delay at this stage, and which finally did well without operation that the point of greatest tenderness so anxiously

investigated at each visit was more or less remote from the usual region. 4. If vomiting is not marked. It is not usually a prominent symptom of this stage of appendicitis in cases which lead to recovery. It will almost always be found present in an inverse relation to the looseness of the bowels. Its absence is a very favourable circumstance, and always, and I believe justly, influences my prognosis. 5. And, finally, I am less anxious during this period of delay if, without marked change in the general condition, increased resistance, slight dulness, and the presence of a mass recognisable by palpation indicate that a localised abscess is forming, shut off by adhesions from the general peritoneal cavity.

CASE 2.—A young man had the usual symptoms of a moderate attack of appendicitis for three days. At the end of that time the conditions present were: rigidity of the abdominal muscles over the right iliac fossa; slight tympanitic distension of the same region; temperature 101.5° F. and pulse 110; marked tenderness at a point just above Poupart's ligament at the junction of the middle and inner thirds. He had been continuously on salines. His stomach was retentive, but there had been no bowel movement for two days. He was getting no food. I was strongly inclined to operate, but delay for twelve hours was decided upon, and at the end of that time there was such marked amelioration of all the symptoms that operation was not further considered.

We may pass in this condition of uncertainty into the period extending from the third to the fifth day with very little alteration of the symptoms, but usually during this time one of the three events already mentioned will occur. If the bowels continue to act spontaneously or with mild laxatives, if the tympany, which may be quite marked, begins to decrease, if the fever lessens, and especially if tenderness remains well localised and tends to subside, the prognosis is, on the whole, favourable, although the patient is unquestionably in grave danger during every minute of this time. If no amelioration of these symptoms occurs, although no new ones develop, the case at that period, from the third to the sixth day, becomes one of the most anxious and trying with which either physician or surgeon can be confronted. It is the time at which, as Richardson has tersely put it, we may feel that it is "too late for the early operation and too early for a safe late operation." It is probable that adhesions have formed, offering a certain degree of protection against general infection; but experience shows that in many cases they cannot be depended upon, and we may find at any visit that the tenderness and tympany have increased in intensity and become more widely diffused, that vomiting is more frequent and uncontrollable, that the fever has risen to 104° or 105° F., or, more onerous still, has disappeared leaving the temperature subnormal; in other words, that the general peritoneum has become involved. If, with the fear of this occurrence before us we proceed in such a case on the fourth or fifth day to removal of the appendix we do so with the knowledge that there is much risk of breaking up the recent and delicate adhesions which have thus far been the patient's safeguard, and we know that it is not always possible under these circumstances, however thorough and minute our precautions, to prevent a spread of the infection. With absolutely identical symptoms on which to base a prognosis at this stage, any two cases may go on, one to recovery, the other to death, and the same remark applies to the result of operation. On the whole, however, this very uncertainty tends to favour operation in spite of its undoubted dangers. We are now dealing with a case of circumscribed peritonitis threatening to become general. The infection which is giving rise to it is a progressive one. Ziegler and others have shown that the effect of injecting a culture of the colon bacillus into the peritoneum of animals varies, other things being equal, with the dose. In the mildest cases an illness, in which diarrhoea is a symptom, is followed by recovery. In another grade a localised purulent peritonitis is produced, running a slow course. If the dose is larger a fatal diffuse fibro-purulent peritonitis follows, and, if still larger, death may occur from acute sepsis before there has been time for any of the phenomena of peritonitis to develop. The peritoneum has thus undoubted ability to take care of certain quantities of bacterial poison, but succumbs to larger ones, and for this and other reasons it cannot be questioned that if the choice had to lie between infection, during, and because of, an operation on the third or fourth, or fifth day, and on the other hand an operation to which we are forced on account of spontaneous infection at some later period, the former course is by far to be preferred.

What we need is information as to what symptoms indicate a persistent circumscription of the inflammatory action, whether it be suppurative or otherwise, and what symptoms point to an extension to the general peritoneum. Treves has shown that in the larger proportion of cases of fatal peritonitis the leading symptoms are those of poisoning and not of inflammation. Extension of the latter to the general peritoneum means that a large part of the enormous area of that membrane takes part in the absorption of the products of the bacterial infection. It should not be forgotten that the cases in which suppuration is most pronounced are among the most favourable examples of peritonitis, and that the most hopeless cases are often among those that show the least inflammatory changes. At present we have no safe rule to guide us as to the greater or lesser likelihood of generalisation in any particular case of appendicitis in the stage of circumscribed peritonitis. As we know clinically that localised varieties of peritonitis and circumscribed exudations are very rare in the area occupied by the small intestine, and as we know both clinically and experimentally that the peritonitis which involves its covering is of the most violent and intense variety, it might perhaps be safe to say that where the area of tenderness is small and distinctly confined to the cæcal and pericæcal area the prognosis is more favourable than when it extends beyond that region, and the latter occurrence might thus be regarded as pointing in the direction of generalisation, and therefore of operation; but I have no reliable observations to confirm this view, which may be unsound as a practical guide.

Of the phenomena which mark the actual onset of diffused peritonitis perhaps the gradual increase of tympany and tenderness and persistent vomiting is the most significant. If operation is done in a doubtful case at this time it will differ from the procedure already described in the necessity for thorough cleansing of the peritoneal cavity, if it is found to be infected, and in the employment of drainage. It differs also in the great care which must be taken, if a localised cavity containing purulent or sero-purulent fluid is found, to avoid making a communication with the general cavity of the abdomen. Large numbers of cases show now beyond all doubt that it is infinitely better to leave the appendix than to make a prolonged search for it or to employ much manipulation in freeing it from adhesions preparatory to removing it. The later the time of operation and the stronger and firmer the abscess wall, the safer the operative procedure becomes, but in every case and at every period if there is a circumscribed abscess it is poor surgery to insist upon finding and taking away the appendix in the face of obstacles. I have often removed the appendix when it was easily found, but I have oftener left it without more of a search for it than could be made in two or three minutes.

CASE 3.—A woman who was suffering with an attack of appendicitis of a chronic type had been ill for more than two weeks. There was a thick-walled tumour in the right iliac fossa. An incision through thickened and oedematous tissues gave vent to a large quantity of fetid pus. Digital exploration with the finger showed dense adhesions in every direction. No further search for the appendix was made. A drainage-tube and iodoform gauze were inserted, and the angles of the wound closed. Recovery was uninterrupted.

In a series of cases of perforative peritonitis reported by Kaiser, of six examples in which the exact point of perforation was never found five recovered. In seventeen cases in which Fowler did not remove the appendix and which recovered there was recurrence in only two within the next two years. The remainder had gone for variable periods, three of them for between three and four years, without any symptoms. I have now had fifteen such cases myself, and in none of them have I heard of any subsequent trouble other than the occasional occurrence of a small fecal fistula which sometimes relapsed once or twice, but has thus far finally closed spontaneously and permanently in every instance.

CASE 4.—The patient was a woman fifty years of age. She was of low intelligence and no satisfactory history could be obtained. After admission to the hospital she complained bitterly of pain in the left iliac region and only later of pain and tenderness on the right side. Vaginal examination revealed a firm, resistant, tender mass on the left side and nothing abnormal on the right side. Her temperature was 101° to 103° F., and her pulse 110. There was dullness over the right flank. There was general tympany; some general tenderness was present, more marked, however, on the right side and at McBurney's point.

Borborygmi could be heard by abdominal auscultation. The bowels acted freely under salines, after which there was a drop of two degrees in temperature and some improvement as to her feelings, but the local phenomena remained unchanged. An incision gave exit to perhaps twenty-four ounces of horribly fetid pus, which had been under great pressure. Inspection showed the distal extremity of the appendix projecting into the cavity from among a mass of intestinal coils covered with lymph and firmly matted together. No effort was made to remove it. The patient has done well.

The same reasons that forbid interference under these circumstances have prevented me from looking long or earnestly for other foci of suppuration. Sometimes they may easily be recognised and opened into the larger abscess cavity by the finger, but when this is not the case I think the patient's chances are better if the possibility of their presence is disregarded, as they are found in only a minority of cases, and they not infrequently open spontaneously into the original cavity. Irrigation, drying the cavity and dusting it with iodoform, the insertion of a large thick-walled rubber drainage-tube, and light packing with iodoform gauze complete the operation as I am in the habit of performing it. The prognosis during all this period is in direct relation to the localisation of the symptoms and of the absence of general sepsis. Accordingly a well-marked tumour, a moderate fever, a high tension pulse not of excessive frequency, a limitation of the tenderness to the right iliac region, even if there it be exquisite, and evidence of continued peristalsis, such as the recognition of borborygmi by abdominal auscultation, are all favourable. But at this or at any stage of the disease, from the earliest onset to the period of complete recovery, we may meet with quite a different set of symptoms. In the beginning the torsion of the appendix may be nearly or quite complete; or with moderate torsion there may be an exceptionally imperfect blood-supply; or in either case the bacteria present may be of especial virulence or in unusual quantity; or finally the resistant power of the individual may be markedly defective. According to the varying predominance of one or the other of these factors we meet clinically with types of cases directly comparable with those conditions produced in animals by experimental inoculation with the colon bacillus. Two of these we have now very imperfectly considered—the mild cases, in which the peritonitis is an inconsiderable element and which usually end in recovery, and the cases of distinct circumscribed peritonitis running a more chronic course and ending either in resolution or, if more severe, in localised suppuration. Either with or without these precedent stages we may have a general peritonitis. If this results from spread by continuity—the usual mode in which a localised peritonitis becomes general—or by infection through the lymphatics of the appendix and meso-appendix, or by a slow leakage of inflammatory products through the appendix wall, or by the migration of bacteria along the same channels, its approach may be slow; if it follows the rupture of an abscess it will be much more rapid.

CASE 5.—The patient had been apparently convalescing from an attack of appendicitis when, contrary to orders, he walked from one room to another. He was at once seized with a violent abdominal pain, which was immediately followed by distension, vomiting, and symptoms of shock. I operated a few hours later, irrigating and draining the peritoneal cavity, which contained a large quantity of pus, but he died the next day.

But in either event it is usually of the fibro-purulent variety and is accompanied by much exudation. The patient soon presents the typical picture of diffused peritonitis—the incessant restlessness, the greatly distended abdomen tender everywhere to the lightest touch, dorsal decubitus, constant vomiting of small mouthfuls without much effort, thoracic respiration, obstinate constipation, absence of intestinal sounds, and high fever, followed towards the end by subnormal temperature, cold sweats, and collapse. It is of great interest, however, to note that even the cases which tend to run this course will occasionally recover when seen and operated on at the very onset of the generalised symptoms. In fact, if operation precedes the development of septic paralysis of the intestines a very fair percentage of such cases will recover. But after the latter phenomenon has appeared I regard the case as absolutely hopeless. If it is unmistakably present it is, I think, best to decline to operate. But if there is any doubt about it it is well to open, irrigate, and drain the abdomen. The suppurative cases are among the most favourable examples of peritonitis, whether general or localised. When localised they are very

favourable, and even in these general septic cases the more the suppurative process overshadows the toxæmia the better are the patient's chances. It may be well to note a possible explanation of this fact. Reichel some years ago determined that by gradually administering increasing doses of pure cultures of pyogenic micrococci to the peritoneum of an animal an immunity against an extremely large dose of this poison could be produced. The same immunity was acquired in the same way against the introduction of a sterile filtrate from the cultures and against the metabolic products of the staphylococci. Control experiments were uniformly fatal in animals not previously prepared. Attention has been called by Binnie to the clinical differences between the rupture of a chronic pyo-salpinx, even if of enormous size, and a case of very acute or so-called fulminating appendicitis with gangrene of even a small portion and escape of its contents.

CASE 6.—I saw some time ago a child in whom within a very few hours of the onset of the symptoms there was gangrene not only of the appendix itself, but also, and apparently as a result of an overwhelming bacterial infection, of an adjacent portion of the ileum. Distension was enormous. An enterostomy was done with a little temporary relief, but the child died soon afterwards. The chances of the patient, if operated on in a reasonable time, are far better in the former than in the latter case. Operation within three hours of the very first symptoms of such an event has failed to save the patient. He dies, as Treves has emphasised, not from the inflammation, or still less on account of any suppurative process, but from a profound toxæmia. In the pyo-salpinx there has been an opportunity for slow auto-inoculation. In the rapid gangrene of appendicitis there has been no time for this process. It is in such cases that we find the flat, silent abdomen indicative of absolute paralysis of the whole intestinal tract, and we have all the symptoms of shock and collapse. Here operation also is useless and to be avoided. But in the suppurative cases, for both the practical and theoretical reasons above given, if any sign of peristalsis remains—and this is the very best indication I know of as to interference or non-interference in these excessively grave cases—it is better to open and irrigate even if the patient is liable to die on the table. Occasionally a desperate and apparently hopeless case will be saved. The best immediate indication of gross perforation of the appendix with escape of its contents into the general cavity is sudden, violent, excessively acute pain, followed by rapid change of temperature, either rise or fall, and marked increase of the pulse-rate with diminution of volume and force. If the sepsis is profound the abdomen may be flat. If a little less in degree it may be barrel-shaped. Vomiting is usually a conspicuous symptom of this as it is of other forms of perforative peritonitis except that resulting from perforation of the stomach. It often shows its usual inverse relation to normal peristalsis. Of course in these cases operation must be immediate, and even then the mortality has been, and doubtless will be, for many years enormous. There remains to consider briefly the subject of recurrent and of chronic relapsing appendicitis. If, as I believe, various mechanical factors enter into the production of acute attacks, and if quite commonly those factors are brought into play by digestive derangement, and if an acute attack does not of necessity leave a permanent lesion of an infective type it is obvious that a patient may have two or even more mild attacks and safely decline operation. If, however, after any and every inflammation of the appendix the patient is left, as has been asserted, with what is practically a charge of dynamite in the abdomen, operation should be much more frequent than it has yet become. We shall do well both in discussion and in practice to separate the recurrent from the chronic relapsing cases. The former are well illustrated by the following case.

CASE 7.—In December, 1889, a man aged thirty-eight years had a mild attack of catarrhal appendicitis. He was ill for two or three days. He was treated by rest, starvation, salines, and calomel. His attack followed immediately upon a too hearty meal of broiled lobster after a day's shooting. In 1890 he was in New York on a visit and had another attack. I went to see him, meeting in consultation a well-known surgeon who had been called in at once. We agreed as to the undesirability of an operation at that time, but later disagreed, the New York surgeon advising removal of the appendix as soon as convalescence was once established, and I dissenting. I based my advice on the fact that the second attack, like the first, was clearly due to over-eating when tired, and especially on the circumstance that it again

followed a meal of broiled lobster. Moreover, neither attack had been of a dangerous type. The opposing views were submitted by the patient at my suggestion to Dr. Agnew, who decided in favour of delay, and subsequently to Mr. Treves in London, who coincided in that opinion. The patient has never had another attack. I have seen many such cases and at present I feel quite clear that the outcry for operation after one or two such attacks is based on conceptions of the etiology and pathology of the disease which are so incorrect that they entirely vitiate the arguments founded upon them. In chronic relapsing appendicitis the case is somewhat different. The interval then is not one of entire health; there are digestive disorders, flatulence, constipation or diarrhoea, and pain in the right iliac fossa aggravated by motion or exercise or fatigue. The attacks themselves are of a higher grade of severity, are accompanied by the appearance of a tumour, which often never entirely disappears, and by distinct evidence of localised peritonitis. The general health suffers severely and the patient is apt to be anæmic and emaciated.

CASE 8.—A girl aged ten years was reduced to a condition of such chronic invalidism and exhaustion that even during an interval it was a question whether she could survive the journey to Philadelphia; and yet the operation was of the easiest type, completed in ten minutes without trouble. The appendix was thickened and twisted and diseased, but had no important adhesions. The improvement in health was immediate and has been continuous.

In the majority of cases which finally require operation, especially in those in which the persistence of the local symptoms during the interval is marked, pus is present in small quantity and surrounded by thick firm adhesions. Even these cases of chronic relapsing appendicitis do not invariably require operation. In some instances I have suggested it and then have acquiesced in the patient's request for a period of delay, which has now in several cases extended over some years and seems likely to be permanent. There is good reason for believing that the mortality of the operation in skilful hands will be a low one. The experiments of Reichel already alluded to demonstrate beyond a doubt the possibility of a certain immunity resulting from auto-inoculation with pyogenic material. There seems to be good reason for believing that this comparative invulnerability thus acquired renders the peritoneum more indifferent to traumatism than in its normal condition. It is a clinical fact that an intra-peritoneal operation on a subject who has had several attacks of subacute or chronic peritonitis is, *ceteris paribus*, a less serious affair than if the same operation is done on a patient whose peritoneum has hitherto been uninvaded by disease or for operative purposes.

CASE 9.—In a relapsing case the appendix was buried in dense adhesions posterior to the cæcum and was firmly adherent by its tip to the iliac vein. The union was so intimate that I tied off both tip and base and removed the intermediate portion, which showed a small perforation. There was present a general plastic peritonitis. The patient, who had only recently recovered from a severe attack, was extremely emaciated and had the typical facies abdominalis, and yet six hours after the operation, which took three-quarters of an hour, his temperature was normal, his pulse 102, he had a movement of the bowels, and expressed himself as feeling better. He is now making an excellent recovery.

If the indications for operation are clear I think that the question as to whether it shall be done between or during attacks must be unhesitatingly decided in favour of the period of quiescence, the operative difficulties being then much less, especially as regards the important question of possible general infection. In the recurrent type, if operation is to be considered at all, it would be well to take the inappreciable risk of waiting for another attack which may never come. In the chronic relapsing cases, however, if the surgeon in deciding upon operation limits himself to the following indications formulated by Treves, which fairly express those of many surgeons in this country, myself included, he had far better take advantage of the interval. Operation is indicated when (1) the attacks have been very numerous; (2) the attacks are increasing in frequency and severity; (3) the last attack has been so severe as to place the patient's life in considerable danger; (4) the constant relapses have reduced the patient to the condition of a chronic invalid and have rendered him unfit to follow any occupation; and (5) owing to the persistence of certain local symptoms during the quiescent period there is a

probability that a collection of pus exists in or about the appendix. The operation itself may be one of the easiest in abdominal surgery or so difficult as to be impossible in its entirety if due regard is had to the survival of the patient.

[It has been found necessary to publish merely a selection of the cases quoted, on account of pressure on our space.—ED. L.]

NEUROLOGICAL FRAGMENTS.

By J. HUGHLINGS JACKSON, M.D. ST. AND., F.R.S.,
PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND
EPILEPTIC; CONSULTING PHYSICIAN TO THE LONDON HOSPITAL.

(Continued from p. 275.)

NO. XIV.

THE LOWEST LEVEL OF THE CENTRAL NERVOUS SYSTEM— THE STUDY OF TABES DORSALIS, AND SOME OTHER NERVOUS MALADIES, AS OWING TO DISEASE OF THIS LEVEL AND ITS IMMEDIATE CONNEXIONS.

I HAVE¹ implied that tabes dorsalis should be considered as a disease of the Lowest Level of the central nervous system. This level is, I believe, much the same as Marshall Hall's "True Spinal System." It is necessary to say something of the higher levels; we are concerned with them as well as with the lowest level in an analysis of the symptomatology of tabes; obviously we have to take them into account when dealing with the ataxic gait; walking is of cerebral initiation, although largely of lowest level performance.

I divide the central nervous system into two Sub-systems—Cerebral and Cerebellar. The lowest level of the cerebral sub-system is also, I suppose, the lowest level of the cerebellar sub-system; it is the cerebro-cerebellar level. However, no motor connexions² between the cerebellum and the spinal cord (motor centres of the lowest level, as I should say) have been yet proved to exist. There certainly are afferent fibres from certain centres of the cord to the cerebellum. I shall, for the most part, ignore the cerebellar sub-system in this and in subsequent notes, and shall speak of the lowest level as if it were the lowest level of the cerebral sub-system alone.

The foregoing and what is to follow on the hierarchy of nervous centres is, of course, hypothetical.

Each of the three levels of the cerebral sub-system is sensori-motor,³ but I shall limit illustration to the motor provinces of the levels (companion sensory provinces being understood). (1) The anterior horns of the cord and the motor nuclei of cranial nerves—a homologous series of lowest motor centres—make up the (basis of the) motor

province of the lowest level. (We may say that the motor centres of this level are a series from the nuclei for ocular movements to the anterior horns for movements of the perineum; perhaps, in another way of speaking, we may say that it extends from the tuber cinereum to the conus medullaris.) (2) The centres of the Rolandic regions of the cortex make up the motor province of the middle level. (3) The centres of the præ-frontal lobes make up the motor province of the highest level. I am, however, I fear, almost alone in the supposition that the præ-frontal lobes are motor.

The foregoing account of the constitution of the lowest level, merely provisional, is incomplete; several centres, among them the gracile and cuneate nuclei, have been ignored. Even so far as the account goes it is in mere outline. In particular the morphological groups of cells, anterior horns and motor nuclei of cranial nerves, which I call motor centres of the homologous series, ought, so far as our present knowledge permits, to be distinguished into centres proper. I shall return to this subject and shall in another note speak of Superior Centres of the level, to which centres of the homologous series are subordinate. It is because there are superior centres that I spoke of the homologous series of motor centres (anterior horns and nuclei of motor cranial nerves) as making up the basis of the motor province of the lowest level.

Manifestly in very many cases of tabes dorsalis there is disease of more than of elements of the spinal cord. But it was a blunder to speak of this malady as I did by implication (*loc. cit.*) as being owing to disease of the lowest level alone, of its intrinsic elements only. The intrinsic elements, the elements of the level itself, are a series of centres with their interconnecting fibres.⁴ What I call extrinsic elements are fibres which, although in some of their course part of the morphological masses, cord, medulla, pons, &c., are not elements of the anatomico-physiological community I call lowest level, but are (a) fibres connecting centres of the level with parts of the body (fibres extrinsic downwards), and (b) fibres connecting its centres with centres of higher levels (fibres extrinsic upwards).

I will, for illustration of the terms used in the foregoing, take the case of the Ataxic Paraplegia of Gowers. There is in this malady disease of fibres of the posterior columns (fibres extrinsic downwards) which connect centres of the lowest level with parts of the body; there is also disease of fibres of the pyramidal tract⁵ (fibres extrinsic upwards) which connect centres of the lowest level with those of a higher, the middle, level. So far, although there is disease of the morphological mass, the cord, there is no disease of any part of the lowest level itself. If in a case of ataxic paraplegia, muscular atrophy were to supervene due to disease spreading to anterior horns, there would then be disease of elements of the level itself, of some of its motor centres (intrinsic elements).

Fibres of the pyramidal tract are fibres extrinsic upwards of the level not only within the cord, medulla and pons, but also in their further course (through the crus cerebri, the internal capsule and the corona radiata) to the motor province of the middle level. In the case of hemiplegia, from destruction of motor fibres of one internal capsule, there is a negative lesion of fibres of the same tract as there is in lateral sclerosis of the cord, of fibres extrinsic upwards; or equivalently there is a negative lesion of fibres inter-connecting motor centres of the lowest level, and motor centres of the middle level. Fibres of the posterior columns of the cord are extrinsic downwards of the level as much as their continuations are in their after course to the periphery.

To return to tabes dorsalis. Certain extrinsic elements of the lowest level are those especially diseased in many cases of tabes. Speaking with regard to one symptom, ataxic, fibres of the posterior columns are sclerosed (negative lesion), and these, though solidly part of the morphological mass, the cord, are extrinsic elements (downwards) of the anatomico-physiological community I call lowest level. To illustrate more particularly: certain fibres of Burdach's column are extrinsic downwards all the way from the cuneate nucleus, a lowest level centre, to the periphery.

⁴ Although I use the words "connexion by fibres" that expression is not to be taken literally; it is to be taken as standing for any sort of junction, definite or indefinite, or, so to say, for any contrivance by which different nervous elements can influence one another.

⁵ Fibres of the pyramidal tract are chiefly affected in the lateral sclerosis of cases of the ataxic paraplegia of Gowers, and in one or two cases the sclerosis was limited to fibres of these tracts. Gowers, "Diseases of the Nervous System," vol. i., second edition, p. 456.

¹ Brit. Med. Jour., July, 1893.

² Marchi has described descending degeneration of fibres of the circumferential part of the antero-lateral column of the cord after extirpation of one lateral half of the cerebellum. But his observations have not been confirmed by Ferrier, Aldren Turner, and Risien Russell.

³ Although in the text I speak of the middle and highest levels as sensori-motor, I ought to say that Charlton Bastian has long held that there are no motor centres of the central nervous system higher than the anterior horns of the cord and the motor nuclei of the medulla, pons, and aqueduct of Sylvius. He believes that the Rolandic region of the cerebral cortex is sensory and that it is the region in which are registered the mixed body of impressions accruing from our different movements—these being in part superficial, cutaneous, impressions, and in part deep impressions of various kinds emanating from muscles, fasciae, tendons, and articular surfaces. He contends that, "A mixed body of impressions of this kind is evoked as a result of every movement, and this group of impressions is revived in memory as though it were a simple impression immediately anterior to the reproduction of each of such movements" ("Hysterical or Functional Paralysis," 1893, p. 797). Hence he calls the centres in which such impressions are registered Kinæsthetic Centres. He, of course, agrees with those who hold that the centres of the Rolandic region are motor, that upon destruction of these centres there ensue paralysis and "descending" degeneration of the pyramidal tract; but he thinks that the fibres of this tract are not motor although efferent from the sensory, that is, Kinæsthetic, Centres of the Rolandic region to the anterior horns of the cord and motor nuclei of cranial nerves. The centres of the Rolandic region are, on Bastian's view, at once the receivers of fibres from contracting muscles and other coacting parts and the givers-off of fibres (efferent not motor) to the anterior horns which, with their higher homologues (nuclei of motor cranial nerves) are the sole motor centres of the central nervous system. He thinks too that discharge beginning in this or that part of the Rolandic region produces convulsion by intermediation of anterior horns &c., beginning in this or that part of the body. Bastian's opinions on the nature of the representation by the Rolandic region are being accepted by an increasing number of eminent neurologists. Those who agree with him will, I hope, have no difficulty in substituting his terms and the opinions they imply, for the terms and opinions set forth in the text.

Still I think *tabes* should be studied *with regard to the lowest level*, as elements intrinsic and extrinsic of different regions of it are diseased. What I call extrinsic elements, although no part of the level itself, are fibres *directly* connected with its centres. It is convenient to use such terms as "medulla region" and "cord region" of the level, and such as "dorsal" and "sacral," and also "spinal" and "supra-spinal" region of the level.

Tabes is in some cases a malady made up, so to say, of several different sub-maladies. Numerous parts (theoretically all parts of the body, if we take numerous cases to fill up the type), are "fields of symptoms" in this clinical entity. If *tabes* be owing to disease of intrinsic and extrinsic elements of different regions of the level (not of those of its cord region alone), there should at least be a series of *symptoms* referable to disease of extrinsic and intrinsic elements of several (theoretically, if we take many different instances, of all), regions, supra-spinal as well as spinal, of the level. This is in accord with the evolutionary status of the level. For its centres represent all parts of the body—motorily all parts from iris or ciliary muscle to sphincter ani and—with the exception of Superior centres of the level—represent all parts directly, or by intermediation of ganglia of the sympathetic. There are in some cases of *tabes* symptoms referable to disease of extrinsic or intrinsic elements of or towards the two extremes of the level—the Argyll-Robertson symptom and incompetence of the sphincter ani⁶—and there are in some cases symptoms referable to several regions of the level between its extremes. What is of more importance—speaking now with reference to the suggestion that *tabes* may be regarded as a series of lowest level sub-maladies, not merely as a series of symptoms—is that the lowest level in comparison with the higher levels represents parts or systems (digestive, circulatory, &c.), of the body in detail; it represents them (I say again, in comparison with the higher levels), with considerable, not complete, independence of one another. And since the several parts or systems thus represented are exceedingly different, we have in cases of *tabes* sub-maladies so diverse as, to mention but some of them, Rectal Crises from disease of intrinsic or extrinsic elements of the sacral region of the level, Ataxy of locomotor movements of the legs from disease of extrinsic fibres (fibres of the posterior columns), in its lumbar regions, Laryngeal Crises from disease of extrinsic or intrinsic elements of the medulla region of the level, and the Argyll-Robertson Symptom from disease of intrinsic or extrinsic elements of a region of the level higher than its pontal region. There are, in cases of *tabes*, ocular, laryngeal, gastric, intestinal, locomotor, vesical, rectal and sexual sub-maladies. For the interpretation of at least some of these sub-maladies, we shall have to take into account Superior centres of the level.

I will stay to speak briefly and in outline of the evolutionary constitution of the lowest level, so far as I have incompletely defined it, dealing only with the motor elements of this sensori-motor level.⁷ There are four factors in evolution. The lowest level (that is, in comparison with higher levels of the cerebral sub-system, say, with its highest level, (1) represents few *different* movements (little differentiation) little complexity; it (2) represents movements of little definiteness, movements for less particular ends (great generality, otherwise little specialisation); (3) its centres represent in detail—that is, each centre represents some district of the body (little width of representation by each centre, that is, little integration); the centres of the level are (4) little inter-connected (little association of centres; little coöperation).

Whilst saying that the lowest level is least complex, &c., and that the highest level is most complex, &c., we must bear well in mind that the former is the most strongly organised and therefore the least modifiable of all the levels; and that the latter is least strongly organised, and, therefore, the most modifiable of all the levels. Most generally the more simple (less complex), &c., a centre the more strongly it is

organised and the less is it modifiable; the more complex (less simple), &c., a centre the more weakly it is organised and the more is it modifiable. Were not the cardiac, the vaso-constrictor, and the respiratory centres of the lowest level more strongly organised *inheritedly* than are the centres of the highest level, life would be impossible; if the centres of the highest level (those concerned during mentation) did not continue to be (in comparison with those of the lowest level) little organised and thus very modifiable, few new acquisitions would be made. The centres of the lowest level, to speak figuratively, make few mistakes, but do not develop much after birth in comparison with those of the highest level; the centres of the highest level make many mistakes, are less prompt and sure in their operations, but after birth they develop very much in comparison with those of the lowest level. And as to the fourth factor of evolution: whilst the centres of the lowest level have few inter-connexions and those of the highest many, the inter-connexions of the former, being strongly organised, ensure much more nearly inevitable coöperation than do the weakly organised connexions of the latter.

Perhaps the four assertions made under the formula may be thought to apply only to the centres of the lowest level which are concerned with organic duties. The centres of the lowest level which subserve the highest level in animal duties (to speak popularly, "which act under the command of the will") are by themselves little without the higher levels: on this matter I remark later. I submit that to centres of the lowest level concerned with organic duties the formula does apply. I limit further remarks to representation of the parts engaged in these duties; the lowest level by itself represents them very efficiently. The operations by the digestive, circulatory, and respiratory systems are certainly (1) simple, few *different* movements (obviously in the case of muscular walled tubes, arteries and intestines, the movements of which parts can differ but little from one another); the movements are for (2) very general ends, for in one case, aeration of the blood at all times; (3) each of its centres represents some district of the body (representation by the lowest level in detail); (4) the centres representing the several systems are in but little coöperation (in comparison with those of the higher levels).

To say that the lowest level represents organic (visceral) parts, including, of course, their apparatuses, in detail (Factor 3) may seem untrue; I will consider the case of the respiratory system. I have so far been dealing only with what I called the homologous series of centres of the lowest level; centres of this series do represent the respiratory apparatus in detail. There are centres (laryngeal) in the medulla region of the level for movements of the laryngeal muscles; there are centres in the cervical region (phrenic) for movements of the diaphragm; and there are centres in the thoracic region (costal) for movements of the intercostal muscles. I have yet to speak of Superior Centres of the level. One of these, the respiratory (medulla) centre, governs the respiratory apparatus by inter-mediation of motor centres, laryngeal, phrenic and costal, of the three regions of the lowest level mentioned. But of course this Superior Centre is a part of the evolutionary constitution of the level and must be taken into account. I shall speak on this matter in a future note.

The foregoing, as to the evolutionary constitution of the lowest level, is, as I have several times declared, said of it *in comparison with the evolutionary constitution of the highest level*. The following is, of course, hypothetical. The motor province of the highest level (1) represents most numerous *different* movements (great complexity, great differentiation); it (2) represents movements of great definiteness (great specialisation); (3) its centres represent widest regions of the body, if, indeed, each is not universally representing (great width of representation, great integration); (4) its centres have most numerous inter-connexions (great coöperation). The physical condition for insanity, I mean the condition produced by disease, is a negative lesion of more or less of the highest level—synonymously, anatomical substrata of consciousness, so-called "organ of mind." Although there are different *kinds* of insanity (different insanities) implying disease of different areas of the highest level, yet any insanity is an abnormal state of a whole person; physically there is disease of, or of parts of, sensori-motor nervous arrangements which represent all parts of the organism in most complex, &c., ways. There are different kinds of insanity, but there are no sub-maladies in any case of insanity.

⁶ The topographical extremes of the body are the crown of the head and the soles of the feet, but these are not the anatomical extremes. The soles of the feet are supplied sensorily by the third and fifth lumbar posterior roots. The perineal district is supplied, in part at least, by lower, sacral, roots. The legs are supplied motorily and sensorily by centres of the level above those supplying the perineal district. (See an admirable paper by Allen Starr, Amer. Jour. Med. Sci., July, 1892, one of extreme scientific interest and also of great practical value.)

⁷ Although I use terms which are more familiar to medical men than are the terms Herbert Spencer uses, I am, I believe, essentially adopting his formula of evolution. He is, of course, not to be held responsible for the terms I use nor for their application. I should be sorry if any crudities of mine were imputed to him.

I submit that in tabes each part of the body should be studied in detail, as it is the "field of symptoms"—as each case is a series of more or fewer sub-maladies"—that it is well, for example, to analyse separately the "crises," the abnormal pupillary conditions, the ataxic gait, &c., before we deal with the different sub-maladies we encounter in single cases, as together making up a more or less Compound Malady owing to one kind of disease—destruction the result of one kind of pathological process—of intrinsic and extrinsic elements of different regions of the lowest level. And I submit that tabes should not be spoken of as being owing to disease of the cord, but as resulting from disease of intrinsic and of extrinsic elements of different regions, often supraspinal as well as spinal, of the lowest level.

A SUCCESSFUL CASE OF PYLOROPLASTY.

By RUTHERFORD MORISON, M.B. EDIN.,
F.R.C.S. ENG. AND EDIN.,

SENIOR ASSISTANT SURGEON, ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

A WOMAN aged forty-eight years was sent by Mr. Sheraton of Sedgefield to consult Dr. Drummond, who placed her under my care. The patient was suffering from vomiting and gastric pain. Her illness had commenced five years previously with an attack of vomiting. Similar attacks recurred every three months or so. Since the first seizure she had been unable to take any but the lightest forms of food. Beef or any heavy meal brought on an attack. In the early part of last year the attacks of sickness became more frequent and were accompanied by pain. Since the middle of July, 1894, she had been a complete invalid, with the following symptoms: For two or three days, provided she took very little food and that only of a liquid or farinaceous kind, she would feel fairly well; then a "lump" would gradually form in the umbilical region, producing sensations similar to those experienced during the later stages of pregnancy when the child is moving vigorously about. The "lump" after a time became hard and painful, and violent vomiting accompanied the pain. After lasting for two or three days these troubles disappeared, and for a short time relief was obtained, so that each week was divided into two nearly equal periods—one of pain and sickness, the other of comparative ease. The vomited matter had a frothy, yeasty appearance, an offensive odour, and in quantity always exceeded what had been taken. Early in July she ate a small portion of cabbage, and for three days afterwards she noticed traces of it in the vomited matter. Latterly she had observed that the vomit contained material like coffee grounds and that her stools were black. Her previous health had been good except for a liability to indigestion, more marked during the last twenty years. She had had seven children and one miscarriage. A sister had died from phthisis at the age of twenty-six years. There was nothing else worthy of note in her family history. On Oct. 6th, 1894—i.e., two days after coming to Newcastle—the ordinary vomiting attack came on. Nothing was allowed by the mouth, and nutrient enemata were ordered. On the 7th the patient vomited, from 3 A.M. to 10 P.M., three pints of yeasty, fetid, brownish fluid. She had passed a restless night. On the 8th she vomited about ten ounces of blood. The nutrient enemata were ordered to be continued. On the 9th she vomited some blood at 11 A.M., just before I saw her for the first time. Dr. Drummond and I agreed to wash the stomach out. This was done at 2 P.M. Immediately after washing a small quantity of milk, barley water, and brandy were administered. There was no more vomiting at the time. The fluid removed from the stomach was brown in colour, with a fetid, yeasty odour, and contained changed blood. From this time to the date of the operation the treatment consisted of daily stomach lavage, the frequent administration of small quantities of liquid nourishment by the mouth, and the use of nutrient enemata. On Oct. 15th the following note was made of her condition: "The patient is much emaciated and weighs only 5 st. 1 lb.; she has no appetite; the complexion is sallow and the expression anxious; the abdomen is retracted and flat except over the epigastric, left hyperchondriac, left umbilical, and left lumbar regions, which are elevated by the distended and dilated stomach, the shape of which can be fairly made out through the thin and flaccid abdominal walls. On palpation succussion sounds are

elicited, and just above the umbilicus and immediately to the right of the middle line a firm nodule the size of a walnut is to be felt. After the stomach has been emptied by the tube the nodule can be picked up between the finger and thumb. It is movable in every direction and when pressed directly backwards has pulsation communicated to it by the aorta. Percussion corroborates the belief that the stomach is much

dilated. All the other organs of the body appear to be healthy." On Oct. 16th the Heineke-Mikulicz operation was performed. On opening the abdomen the nodule described was found, as was anticipated, to be the pylorus. Taken between the finger and thumb it felt thickened and resisting, as if an indiarubber ring was embedded in it. The stomach was opened one inch above the pylorus and an attempt made

to pass the little finger through this opening into the pylorus. The pyloric orifice was, however, found to be so small that neither the little finger nor a pair of small clip forceps, closed and introduced subsequently, would pass through it. The incision made in the stomach was then prolonged with scissors through the middle of the exposed anterior portion of the pylorus for about an inch into the

duodenum. (Fig. 1.) The pyloric ring was firm and thick. There was no evidence of old ulcer, scar, or puckering. Drawing apart the middle of each side of the longitudinal incision converted it into a transverse one. (Fig. 2.) This position was permanently secured by a first row of sutures passed close to the edges of the incision through all the

coats of the stomach and duodenum, and a second row through the peritoneum only, in Lembert fashion, burying the first. (Fig. 3.) The operation was completed by closing the abdomen in the ordinary way, and occupied half an hour. The patient, notwithstanding her feeble condition, stood it well. Immediately after being put to bed she was slightly sick. For the first twenty-four hours nothing was given by the mouth. Nutrient enemata were administered every two hours. Twenty-eight hours after the operation teaspoonfuls of hot water were given occasionally. On the third day small quantities of barley-water and milk were given by the mouth and the nutrient enemata were continued. On the evening of this day, after having barley-water and milk, she felt a pain "as if the fluid was passing over a raw surface out of her stomach." On the fourth day she had arrowroot and milk, with mutton broth. On the sixth day she complained of feeling hungry, a sensation she had not experienced for years. On the tenth day the dressing was removed for the first time and the wound was found to be entirely healed. At this time she was having regular meals of bread-and-butter, tea, eggs, fish, and potato. During her convalescence the pulse and temperature never rose above normal, and she made steady progress from the day of the operation.

On Nov. 8th (three weeks after the operation) the patient was shown at a meeting of the Northumberland and Durham Medical Society. She was then in good health and weighed 6 st. 1 lb. (a gain of 1 st.). On Jan. 21st, 1895, she writes: "I am glad to say I am keeping very well, and I weigh 8 st. 6 lb. I don't think I ever weighed so much in my life, and nothing disagrees with me."

Newcastle-on-Tyne.

CASE OF GENERAL PARALYSIS OF THE INSANE IN A CHILD.

By JOHN THOMSON, M.D., F.R.C.P. EDIN.,

EXTRA PHYSICIAN TO THE ROYAL HOSPITAL FOR SICK CHILDREN,
EDINBURGH;

AND

W. R. DAWSON, M.D. DUBL.,¹

DEMONSTRATOR OF PATHOLOGY, ROYAL COLLEGE OF SURGEONS IN
IRELAND.

THE following is the record of a case of general paralysis, beginning at the very unusually early age of ten years and eight months in a girl of average intellect, running a course similar to that most commonly observed in women, and ending in death after a steady breaking down of the bodily and mental powers during a period of two years and four and a half months. An interesting point in the clinical history was the presence for about six months of very marked "facial irritability" (Chvostek's symptom). We have recently observed this symptom in another case of developmental general paralysis—a young woman aged about twenty years—and in a case of ordinary general paralysis. In many of the cases of general paralysis beginning in early life that have been reported, congenital syphilis has been looked upon as an important etiological factor.² Whether it was so in the present instance must remain an open question, for, although we could obtain no decisive facts, our investigations left a strong impression on our minds that the presence of syphilis in the parents was quite within the range of possibility. The post-mortem appearances were perfectly typical of advanced general paralysis and put the nature of the case beyond a doubt.

The patient, a girl aged eleven years and five months, was brought to the Dispensary of the Royal Hospital for Sick Children, Edinburgh, on Dec. 7th, 1892. Her mother complained that her daughter was very nervous—constantly shaking—and that she was quite unable to do any lessons. The condition had lasted for more than nine months. The father was a strong, healthy-looking man. He admitted that he occasionally drank too much, but denied having ever had any venereal disease. There was no history of nervous or mental disease in his family. The mother was nervous and excitable; she had the reputation among her neighbours of being intemperate. Her mother's brother became insane

in old age. The patient was the youngest of seven children. One had died from hydrocephalus; two (immediately preceding the patient) were stillborn; the other three were alive, and healthy with the exception of the eldest, who suffered from "abscesses." None of the children had had snuffles or a rash during early infancy. There had been no miscarriages. The mother had good health during pregnancy. The child had no symptoms suggestive of syphilis as an infant, and she had always been looked upon as strong and healthy. Her mother said she was "the most easily brought up of her children," and that she never had any bad habits or mental peculiarities. She was a natural, bright, affectionate child, who did her lessons fairly well and took a good place at school.

Nine months before I (Dr. Thomson) saw her she had been promoted by the schoolmaster of the Board School from the fourth to the fifth standard after some sort of an examination. At that time, apparently, nothing abnormal had been noticed about her by anybody. Shortly after beginning the work of the higher standard, it was noticed that she was quite unequal to it and seemed to be getting less and less intelligent. She was, therefore, after a few weeks, put back into her former class. She was then found by the teacher who had taught her before to have changed very much in her capacity, and to have become so stupid that she could scarcely be taught anything at all and had forgotten a great deal of what she knew quite well before. She could not do the very simplest sums, and it seemed to be impossible to teach her even a single line of poetry by heart. It was also noticed that her speech was slower than it used to be, and that her handwriting was worse, the strokes being "thin and like a saw." At home it was also seen that she was getting more stupid. She had to be told over and over again to do simple things and had to be shown exactly how to do them or she did them wrong—e.g., she tried one day to sweep the floor with the wrong end of the broom. If sent with a message she forgot it unless she repeated it over and over again to herself on the way. Her hands were very unsteady; she often let cups fall, and she dropped her stitches when she tried to knit. No cause could be assigned for the onset of her illness. She had become steadily worse on the whole, although she was sometimes brighter than at other times.

The following are the notes taken at the time:—
"On examination the child is found to be fairly well nourished, but under-sized and poorly developed. Her height is 47½ inches and her weight 4 st. ½ lb. No sign of congenital syphilis can be found. The cranium is normal in size and shape. A prominent ridge is felt in the position of the frontal suture. The palate is somewhat high, but not very abnormal. The teeth also are not abnormal in shape, and the ears are well formed. There is a marked absence of expression about the upper part of her face. The heart, lungs, and abdominal organs are normal. The pulse is 96 to 100 and regular. Her attitude and gait are peculiar. She stands with her shoulders forward and her arms hanging down in front. She always keeps her hands closed pretty tightly, generally over a penny or some other small object, and her mother has difficulty in opening them when she is washing her. In walking she keeps her legs rather far apart, bends her knees very little, and takes small steps. As one of her neighbours says, she 'walks like a baby.' Her muscular movements are accompanied by a coarse tremor. This is very distinctly seen in her hands if she tries to do anything with them or to hold them still and extended; and its traces are very noticeable in her writing, which is very characteristic. The tremor is also extremely marked in her tongue when she protrudes it, and in her lips and lower jaw at the same time. When she puts out her tongue she tries to steady it by compressing her lips tightly upon it. Her voice is slow and hesitating and distinctly suggestive of general paralysis. Her eyes have been examined by Dr. E. E. Maddox, who finds sufficient hypermetropia present to account for her convergent squint and also for her rather small pupils. The pupils react very slowly and only slightly to both light and accommodation. The left is somewhat larger than the right, and both are somewhat irregular in outline. Owing to the child's extreme restlessness and the smallness of her pupils it is found impossible to get a good view of the fundus, but nothing abnormal can be seen. The child is somewhat deaf, especially on the left side. In other respects the special senses seem normal. The knee-jerks are present equally, but not strongly, on both sides. Her mental condition is very dull. She has to be

¹ Dr. Thomson is responsible for the clinical, and Dr. Dawson for the pathological, notes.

² Clouston: *Neuroses of Development*, p. 76. Middlemass: *Journal of Mental Science*, January, 1894.

told several times to do anything before she does it, the delay being evidently due to slowness of comprehension and not to disobedience. When once she understands what is wanted she repeats it over and over again—e.g., she had to be told many times to put out her tongue before she did it, but for some minutes after, when asked what her name was, or any other question, she replied by putting out her tongue. Her mother says that she seems to wander from one subject to another and never to adhere to the same one for any time. She reads aloud pretty fluently, but evidently does not understand what she is reading. She can name any numbers at once, but cannot add 2 and 1 or 2 and 4 together. She can name ordinary articles, such as pencils, penknives, &c., but seems unable to count them if there are more than three. If told to count up to 100 she does so pretty correctly up to 40, but misses a good many of the higher numbers without seeming to notice her mistake. She takes no interest in dolls or in any other amusement. She is very easily frightened by noise, and starts and trembles if spoken to suddenly or roughly. She seems to be annoyed by her own stupidity; she reddens when she fails to answer or to do some simple act; and when she finds herself unable to put on her boots (as happened once, owing to her having laced them up first) she cries with vexation.

During the first few weeks she was under observation she had many hallucinations and delusions. For example, one day she said to her mother that a boy had told her that a little girl she knew well was dead, and she sat looking out on the street for more than an hour, saying that she was seeing the coffin. The child in question was not even ill. Again, she frequently blamed her sister for stealing things from her which she had never possessed, and she several times told her mother that she had met and been spoken to by friends who, as was afterwards proved, had not been in the neighbourhood on that day. At night she usually lay awake a long time talking to herself loudly, and often repeated words over and over again—e.g., "Mary Jane stole the purse and there was sixpence in it." In January and February, 1893, a distinct temporary improvement occurred. The trembling was less, so that she could hold cups, &c., better, and she was more reliable in taking messages and a little quicker in doing what she was told. In February it was noticed that on percussion on the cheek below the molar bone there was marked "facial irritability" on both sides, precisely similar to that obtained in cases of tetany and laryngismus. The pupils became more distinctly irregular in outline. Towards the end of February she began to get worse again in every way. The trembling became so bad that she could not feed herself, and she ceased to be able to thread a large needle or to hold a pen. In March she began to have incontinence of urine both at night and during the day, and also for the first time she seemed to have difficulty in protruding her tongue when she tried to do it. On April 9th it was noticed that she constantly held her body over to the left side both when sitting and when standing, so that the right shoulder appeared to be about two inches higher than the left. This persisted for several days. About this time she became more irritable, starting and crying on the slightest provocation. If left alone she was generally pretty quiet through the day and free from hallucinations, but she was often restless and noisy at night. She could still write, but very irregularly. Towards the end of April she was worse. She sometimes did not know her own parents, and thought that she was away from home. For two days she refused to open her mouth, and had to be fed forcibly with a spoon. In May she improved again very much, getting fatter and more cheerful. Her speech was a little better, and she began again to try to knit. This improvement lasted for about six weeks. In June she gradually became worse again, and began to have prolonged fits of screaming at the pitch of her voice. Sometimes when she screamed she said that a little boy who lived on the opposite side of the street was beating her. On June 26th her mother heard her screaming in the next room, "Go away with you!" "Take it away!" &c., and when she went to see what was the matter she found the child pointing at a fly which was crawling on the table, and saying that it was a big dog and that it frightened her. About this time the child could not be got to put out her tongue or to hold anything in her hand. The "facial irritability" was beginning to be less marked. During July she had several attacks, in which she fell over to the left side and was very weak and confused, but towards the end of the month she improved greatly, recognised her parents, was

less nervous, took her food better, and began again to feed herself for the first time for many weeks. During the autumn of 1893 she continued to lose ground; she became thinner and weaker, and often seemed to be very cold. She could no longer write at all. Occasionally she recognised her parents and friends, but often she did not do so. She was unable to feed herself or to take a drink without help, and never asked for food, although she took it readily enough when put into her mouth. She had complete incontinence of urine and faeces. She usually leant over to the left side as she sat, and from time to time she had "turns," in which she fell to the left on to the floor if she was not caught. The "facial irritability" had entirely gone, and did not return; but she was still very nervous, starting and grimacing if any quick movement was made near her. She often had screaming fits which lasted for hours, and occasionally would laugh for an hour at a time, equally without apparent cause. She often also repeated one or two words over and over for an hour or two at a time, but at other times would sit quite quietly for many hours together. On Oct. 7th, 1893, she was admitted to the Royal Edinburgh Asylum. During her stay there the disease steadily progressed, but no new symptom developed. She gained considerably in weight, but her mental condition was in no way improved. Soon after she was taken home (Nov. 2nd) it was found that she could no longer stand. She lay in her bed all day with her limbs flexed on her body, seeming to notice nothing and rarely recognising anyone, even her mother. Now and then she suddenly distorted her features as if in pain, and she often cried. When told to put out her tongue she would open her mouth, but seemed unable to do more, and when asked to give her hand she moved it towards one a little. She could no longer repeat any words when asked. Within a fortnight of leaving the asylum bedsores began to form on her back and over the trochanters, and they continued spreading in depth and extent up to the time of her death, in spite of careful treatment. In February, 1894, after saying nothing for six weeks, she began again to repeat a few words. Towards the end of the month she improved further, and seemed brighter and happier than she had been for many weeks. On one occasion, when a book was given her upside down, she seemed to recognise the mistake. After February she never spoke at all; she seemed not to understand when asked to give her hand or to put out her tongue, and she steadily emaciated. During May she continued getting weaker. Her temperature was usually 99° to 100° F.; her pulse 130 to 140; and her respiration 36 to 40, and very shallow. Her right thigh was flexed fully on the abdomen and could not be straightened, but the left could be extended almost completely. Any passive movement of her lower limbs appeared to hurt her very much. During June and the earlier half of July very little change took place. On July 18th she became unconscious and remained so until she died on the 22nd. For the last two days of her life there was constant rhythmical rotation of the head to the left and movement forward and inward of her right upper arm at the shoulder-joint.

Pathological report.—The diagnosis received full confirmation from the necropsy, which was made on July 22nd, 1894, twelve hours after death. Although the weather was very warm, post-mortem rigidity had not passed off, and there was little or no lividity. The pupils were of medium dilatation. The body was excessively emaciated, and bedsores had formed over the sacrum and both great trochanters. There was a slight degree of the malformation known as pigeon-breast; the abdomen was strongly retracted, the limbs were more or less firmly fixed in a position of flexion at the knees, hips, and elbows, and the shoulders were also fixed. A small amount of pubic hair was noted, but the figure and mammary development were those of a young child. On examining the head the scalp was not found to be unduly adherent, but the skull-cap, the inner and outer tables of which were thickened (partly at the expense of the diploë), had contracted adhesions with the dura mater, especially along the superior longitudinal sinus. The sinuses contained red and white clot and were engorged, as were the veins opening into them from the pia mater, whilst the dura mater itself was everywhere thickened, and in some places was separated from the bone by a false membrane, the latter a somewhat rare condition, constituting the pachymeningitis externa of German writers.³ In addition to this, however, the dura mater over the whole

³ See, for example, Ziegler: *Pathologische Anatomie*, seventh edition, Band ii., p. 377.

extent of the cerebrum was lined with a false membrane, which varied greatly in thickness, being merely a thin film in the middle cranial fossa, whereas over the parietal regions it was fully a quarter of an inch thick in places. This membrane was adherent to the arachnoid all over the vault, though not very firmly, except in the part corresponding to Broca's lobes, where a fibrous band was noted. It left the cerebellum uncovered, but was observed to pass downwards beneath the pons and medulla so as to invest the spinal cord also. The pia-arachnoid was congested and thickened, especially so along the vessels, and over the surface of the arachnoid a number of fine, white, non-adherent grains were observed, whilst a considerable amount of sub-arachnoid fluid gave the brain a jelly-like appearance when first removed. The pia mater was found to be universally adherent to the cortex over the cerebrum, and there was also an attachment between the anterior lobes of the brain just in front of the genu of the corpus callosum. There was marked superficial atrophy of the brain, most pronounced in the frontal and parietal regions, where the convolutions were very distinct and the sulci wide, and the encephalon as a whole was abnormally small, the cerebrum, cerebellum, pons, and medulla, with the small portion of cord removed with them, weighing only 26 oz. (of which the cerebrum made 21 oz.)—some 10 oz. less than the average at that age. On cutting into the brain the grey matter, both of the convolutions and the basal ganglia, was seen to be of a deep reddish-grey or brown colour, and its vessels were full of blood; but, whereas the cortex was tough in consistence, the ganglia were soft and friable. The former was everywhere atrophied, and in no region could the usual layers be distinctly made out in it. The white matter was pinkish in colour, and though of soft consistence was tough. The ventricles were dilated, and contained some turbid fluid, whilst the ependyma (at least, in the lateral ventricles) was thickened and tougher than normal. Fine granulations were visible on the floors of the lateral ventricles, whilst that of the fourth ventricle was covered with a great profusion of coarser ones. The soft commissure in the third ventricle was exceedingly tough. The choroid plexus of the lateral ventricles was congested and contained some cysts. The cerebellum showed much the same conditions as the cerebrum, except that there was no subdural membrane and the pia mater was not adherent. There was nothing very remarkable about the pons or medulla. The vessels of the cord, as elsewhere, were injected. Had any doubt still remained as to the nature of the disease it would have been completely removed by the study of the microscopic appearances. Sections of the cortex were cut by the modified fresh method of Bevan Lewis from the anterior part of the frontal lobe, the motor area, and the occipital and temporo-sphenoidal lobes, and were stained with aniline blue-black. The pia mater wherever retained was found to be thickened, while the tissue immediately underlying it was fibrillated and contained numerous spider cells. The latter were also visible in the deepest layer of the cortex, as well as (in some places at least) in its thickness, and they were detected in the white substance, especially near some of the arterioles. The capillaries were more prominent than normal, and their nuclei appeared to be multiplied in places, whilst the small arteries frequently showed great proliferation of the adventitia nuclei, and the perivascular spaces sometimes contained masses of pigment. The pyramidal cells, large and small, were in an advanced stage of degeneration, losing their processes and breaking up; but, on the other hand, the cortex contained an abnormally large number of round cells. The changes were unusually uniform all over the brain, but perhaps, on the whole, more advanced towards the anterior part. Sections cut from the cervical region of the (hardened) cord and stained by Vassale's modification of Weigert's method showed much degeneration, which, although somewhat diffuse, was especially marked towards the posterior parts of the posterior and lateral columns, and in a less degree in the region of the direct pyramidal tracts in front. Transverse sections of a nerve taken at random from the cauda equina and similarly treated showed many degenerated fibres. The false membranes, both inner and outer (sections of which, including the dura mater, were stained with hæmatoxylin and eosin), consisted of vascularised fibrous tissue, the most internal layers of which—i.e., those nearest the brain—had in some places acquired a homogeneous hyaline appearance. The vessels of the true dura mater were here and there dilated owing to the increased blood supply required for the new membranes, and the dura mater itself, which

was thickened, contained in places, in its actual substance, structures resembling in every respect the earlier stages in the formation of false membranes—i.e., a network of fibrinous bands containing round cells in its meshes—an interesting fact which was noticed and pointed out to us by Dr. W. F. Robertson. The minute white particles strewn over the surface of the arachnoid were not examined, but they were similar to particles seen by one of us in another case, and which appeared to be composed of fibrin entangling numerous colourless cells. Further observations, however, are required. As regards the other organs, little need be noted. The serous cavities were drier than normal. There was a slight adhesion over the apex of the right lung, and the latter contained a small, well-defined, yellowish nodule, which showed no signs of breaking down, and was possibly of syphilitic origin, as no distinct evidence of tubercle was elsewhere discovered. Both lungs were congested and slightly emphysematous, and the bronchial glands were enlarged, though not caseous. The heart, which was contracted, was healthy, and the vessels were normal, so far as examined; the liver was soft and flabby, with much fatty infiltration; the spleen was pale and soft; the kidneys were congested and fatty, the capsules being adherent in places. There was an hour-glass contraction of the stomach, rather nearer the pyloric than the cardiac end, but the rest of the intestinal tract seemed to be normal. The bladder was greatly distended. The uterus and ovaries were healthy.

FILTERS IN CONNEXION WITH THE SPREAD OF DISEASE.

By HENRY CAYLEY, F.R.C.S. ENG.,

PROFESSOR OF MILITARY MEDICINE, ARMY MEDICAL SCHOOL, NETLEY

THE following two instances of the apparent distribution of disease through the medium of ordinary water filters, such as are commonly used in India, have been kindly communicated to me by Surgeon-Captain Aldridge, A.M.S., who on both occasions had the cases under his observation, and they appear to be of such high interest and importance as to deserve publication in *THE LANCET*. The cholera outbreak at Lucknow is already attracting public attention, and some of its details will now have a special interest. I will merely state the facts as observed by Surgeon-Captain Aldridge. The lesson to be learned from them and the conclusions to be drawn are obvious.

1. *Cholera*.—During the recent very serious outbreak of cholera among the troops at Lucknow the disease was almost confined to the East Lancashire Regiment (in which there were about 135 cases and ninety deaths) and to one ward in the station hospital. Amongst the other troops of all arms, European and native, there were only eight or ten cases in all. The disease was distributed pretty generally through the different barracks occupied by the East Lancashire Regiment; there were cases in ten out of sixteen barrack buildings. In the station hospital men in one ward only were attacked; this was the special ward in which the severe and acute cases of disease were under treatment—chiefly cases of enteric fever. In this ward about seven of the patients were attacked with cholera. The first case occurred about August 1st. In the regimental barracks nine cases occurred between July 19th and 28th. On July 29th about 350 of the men were sent into camp on the brigade parade ground close by, where they remained under the same condition of food and water-supply. Cholera continued among them, and these men were marched on August 1st to camp at Kakra, about six miles distant. Between July 29th and August 9th 117 cases occurred. Amongst the men about 250, who remained all the time in their barracks, there were far fewer cases than among those who went out into camp.

The milk-supply was from cows kept at the regimental barracks; the men consumed very little milk. The same milk was supplied to the married quarters, in which there were only a few cases of cholera, and to the Station Hospital, in which cases occurred in only one ward, and the disease could in no way be attributed to infected milk. The drinking water was from two wells, one for each division of the barracks, a road dividing the two divisions.

The wells are completely closed in and free from any ascertainable source of contamination. The water is pumped up from the wells into the filtering tanks, and thence drawn into buckets and passed through Macnamara's filters. The filtering medium of the tanks consists of sand and gravel. Filter tank No. 1 was recharged with new sand and the water again used on July 14th. The first case of cholera occurred on July 19th, the second case on July 24th, in the part of the barracks using water from this tank. Filter tank No. 2 was recharged with sand on July 21st or 22nd. The first case of cholera among the men using the water from this source occurred on July 24th. The filter-tanks in the barracks occupied by other corps were recharged under a separate contract and at different dates. Those in the barracks occupied by the Royal Irish Regiment, in which only one case of cholera occurred, were recharged six months previously. The mineral water factory of the East Lancashire Regiment obtained water from the same tanks as the barracks of the regiment, and supplied only the regiment and the station hospital. In the latter the aerated waters were chiefly used in the "special" ward in which cholera broke out. The men out in camp, when they moved from the station, had a different water-supply, but the same mineral waters, which were sent out daily in large quantities, as they were considered to be safe for drinking, and the supply was barely sufficient to meet the demand, so that they were drunk at once after manufacture.

The barracks occupied by the East Lancashire Regiment were separated only by a road from those of the Royal Irish Regiment, and the Station Hospital was alongside of the latter. The sand with which the filter tanks were recharged was said to have been procured from the banks of the Gumti River, about two miles from the station; there was at the time cholera among the natives, and, as is well known, the natives regularly resort to the banks of rivers and tanks to obey the calls of nature, to bathe, and to wash their clothes. The sand was said to have been washed and roasted before use, according to regulation, but this was done by the contractor who supplied it, and may have been done very imperfectly. A new pipe water-supply was introduced at the end of July, but the water was turbid at first, and its use discontinued. After a few days it was again brought into use, and for a week or so both water-supplies were used by the men remaining in barracks. On Aug. 9th the supply from the filter tanks was shut off, and cholera ceased from that date.

About Aug. 11th Mr. Hankin made bacteriological examination of the water used at the barracks. He reported as follows: "Water from wells Nos. 1 and 2, no cholera vibrios. Water after passing through filter tanks Nos. 1 and 2, cholera vibrios present in both. Soda-water freshly manufactured from this tank water, cholera vibrios present." This outbreak of cholera was practically limited to the men of the East Lancashire Regiment in barracks and camp and to those in the "special" ward of the hospital. The only condition that was common to these two sets of men and not to the rest of the garrison, and that could be connected with the outbreak of cholera, was the water that had passed through the filter tanks, some of which was used for the mineral waters.

The first case of cholera in each division of the barracks occurred from two to four days after the filter tanks had been recharged with sand, and the first case in hospital was a few days later, in the ward where the mineral waters were chiefly used. Many of the cases in camp occurred at a long interval (ten days) after the men had been removed, and had ceased using the water direct from the filter tank, but these continued to use the freshly manufactured mineral waters. The men sent into camp suffered very much more than those remaining in barracks. The latter used both the water-supplies—that from the tanks and new pipes—and they also consumed much less of the mineral waters. That men sent into camp during cholera epidemics suffer more than those who remain in barracks is by no means an uncommon occurrence, and the thought often presses itself on one that when cholera appears in a community sending the men into camp is a mistake. It is of course the generally accepted practice, founded apparently upon experience, that when cholera breaks out the men should be sent into camp and moved at short intervals, and in India regulations have been laid down in accordance with the idea. But what are the facts? When cholera appears, say, in a regiment, if during the first ten days the cases are at all numerous the men are moved out into camp. It then almost

always happens that for the first few days or the first week in camp the disease increases, it then begins to decline and becomes less severe, and in the course of another week or so it finally ceases, except for a few isolated cases. This is the natural history and behaviour of the disease. In any restricted community it reaches its acme in about a fortnight, then gradually lessens, and in three or four weeks is at an end. Of course, in large towns or widespread communities it lasts much longer, but even in Hamburg the epidemic only lasted for about two months.

Up-country in India outbreaks of cholera almost always occur in the rainy season, when men in camp are exposed to great discomfort and suffering, and, far worse, to the sources of such serious diseases as malaria, dysentery, &c. Clearly they should not be subjected to such exposure unless the benefits are undoubted. With our present knowledge of the various ways in which cholera may be introduced into the system, many of which may be absolutely guarded against, it again requires consideration whether the men may not be safely left in cantonments and every possible precaution taken to prevent the food, the water, and the air (as by dust) being contaminated, and all other possible channels of infection. This can certainly be done more effectually in cantonments than in an exposed camp in the rainy season.

2. *Enteric fever*.—The second instance, an outbreak of enteric fever in the 3rd Battalion Rifle Brigade, occurred at Jullander in 1891 and points strongly to a similar cause. The first case, that of a woman, was admitted into hospital on March 27th. She had been ill in quarters for a few days previously. On April 14th the next case was admitted—one of the men from barracks—and during the next five weeks eleven more cases occurred in the barracks. No direct infection and no pollution of wells seemed to be possible. The milk was from the regimental dairy and seemed to be unimpeachable. The material used in the filter-tank through which all the drinking water passed was sand and gravel. The sand was dug from the side of the river, at the time practically stagnant, and at the spot where the sand was collected, and for a few hundred yards above and below, the clothes of the regiment were washed. The first case, that of the woman, occurred a few days previous to March 27th. The filter tank was recharged with sand from the place indicated on April 1st or 2nd, the woman's clothes having been washed near the spot a few days before. On April 14th the first case from barracks was admitted. Here, again, the evidence is very strong that the sand used in the filter tanks was the source of the outbreak, and the same thing may easily have occurred in numberless other outbreaks. Experiment has shown that no filters, except perhaps the Pasteur-Chamberland, will prevent the passage of pathogenic germs for more than a very short time. The Macnamara filter cannot, therefore, be relied on to free drinking water from such organisms if they be introduced into the water from the sand filter tanks.

SYPHILIS ACQUIRED IN CHILDBED.

By F. D. FISHER, M.B., C.M. EDIN.,

JUNIOR HOUSE SURGEON, ANCOATS HOSPITAL, MANCHESTER.

A SERIES of cases of syphilis acquired in childbed and exhibiting tertiary phenomena rarely comes under observation. The unhappy victims of this misfortune were not in the first instance attended by medical men, but were all delivered by the same midwife, who had been inoculated on the hand with syphilis while nursing a prostitute. All the confinements took place in 1882—six in August, three in September, and one in October. There is no reason to suppose that the midwife ceased to follow her vocation after the latter date, and it is certain that the cases which were traced did not include all that occurred. In none of the cases could any history of inherited or previously acquired syphilis be obtained. Seeing that the events in question took place twelve years ago, and that most of the women suffer from impairment of memory, it is not surprising that their recollection of the dates of the primary and secondary symptoms is very defective.

CASE 1.—This patient was delivered of a child in October, 1882. The first sign of inoculation was a sore situated just within the labia, and not accompanied by any special symptoms. The midwife's explanation of it was that she

had scratched the patient during delivery. Skin eruptions first appeared as "red spots" on the legs, but the body and buttocks were in turn quickly invaded; the period of eruption is not known. The hair then fell off, especially from the crown of the head, and eruptions subsequently appeared on the arms. About two and a half years after the first symptoms she suffered from "fits" during several weeks; they occurred four or five times a week, and generally came on at night; during the attacks she was unconscious, and was said by her friends to have foamed at the mouth and become rigid. There are now numerous scars on the arms and face, and a large scar on the forehead, a little to the right of the middle line, marks the place from which a "tumour" was removed after three years' duration. A yellow, fetid discharge from the left ear commenced twelve months before the operation, and was accompanied by dull pains in the temple and partial deafness; it lasted for twelve months, and the patient thinks it ceased after the operation. Her memory is distinctly impaired, so much so, indeed, that her statements can hardly be relied upon. On the crown of the head there is an ulcer six inches long and five inches in diameter, with irregular edges, a black base, and a very fetid yellow discharge. The movements of the eyeball and the field of vision are now normal, but no ophthalmoscopic examination was made. There is no history of eye disease, but the patient suffered some time ago from diplopia. She now complains a good deal of pains in the back. She has had no more children or miscarriages. This case was not treated in its early stages; at what period treatment was begun cannot be ascertained. The husband was inoculated about a month after his wife, but nothing is known of his symptoms; he died in an asylum five years afterwards.

CASE 2.—This patient was delivered of a child on Sept. 17th, 1882. She had a sore on the vulva, but denies having had any secondary symptoms, and is now apparently quite well. The child was evidently infected from the midwife. The navel became ulcerated and the sore healed slowly under treatment; rashes appeared on the head, body, and buttocks. The child became greatly emaciated, but subsequently gained flesh and appeared to be quite well. The child died when seven years old from accidental burning. The husband developed a sore near the frænum of the prepuce a month after a visit to his wife, and the prepuce sloughed extensively. It was at this period that treatment was begun. He has now a scar in each groin, where abscesses were opened, and he presents the symptoms of locomotor ataxia, with delusions. He does not appear to have had any local paralysis, but has girdle pains round the body, incontinence of urine, the Argyll Robertson pupil, and a typically ataxic gait. His sexual power is now greatly diminished, and his patellar reflexes are lost. No ophthalmoscopic examination was made. Since 1882 the woman has had six children and one miscarriage at the third month. The first and third children are alive, the second died of marasmus, the miscarriage then followed, the fourth child died of paralysis in infancy, and the fifth and sixth children died from marasmus.

CASE 3.—This case is particularly interesting, as its nature was suspected and treatment begun before the stage of incubation was over. The disease ran a mild course. The patient was delivered of a child on Aug. 28th, 1882. Rashes appeared on the back and neck; she lost her hair, and had a sore-throat, followed by "inflammation of the eyes"; her vision is now impaired. The child is alive and well. In July, 1885, she was admitted into the Sheffield Infirmary and operated on for ovarian tumour, twenty pints of fluid being removed. Since then she has had two children, neither of which presented any symptoms of inherited syphilis, and their present condition is very good. The husband states that he never had a sore or secondary symptoms.

CASE 4.—This patient was delivered of a child in August, 1882. The puerperal period was prolonged, "weakness" being assigned as the cause. The secondary rashes were distributed chiefly on the neck and arms, and were attributed by the nurse to "poorness of blood"; the hair of the head and eyebrows also came out. Treatment was begun in January, 1884, seventeen months after inoculation; the medicine caused "fits," which ceased when she took it after food. There appear to have been no eye affections or sore-throat. The woman now enjoys good health, headache and impaired memory being chiefly complained of. One child was born on Dec. 26th, 1888, and is alive and well. In August 1891, there was a miscarriage (period not known)

without apparent cause. Three months after the woman's confinement her husband noticed a sore near the frænum of his prepuce, where there is now a scar. Skin eruptions subsequently appeared, chiefly on his neck and thighs; he also had a very bad sore-throat. About two years after the first symptoms his left nasal cartilage began to ulcerate, and part of it is now absent.

CASE 5.—This patient was delivered of a child on Aug. 12th, 1882. The placenta was retained, and was removed by the midwife who passed her hand into the uterus. The patient noticed a sore on the nurse's finger; it was described as a crush caused by the wringing machine. The first symptoms were observed in October, 1882, when small red pimples appeared all over the body. The vulva is described as resembling raw beef. The patient suffered from loss of hair and prolonged sore-throat; her teeth decayed and broke off. There was also partial deafness and tinnitus aurium, both conditions being due to accumulation of cerumen. In December, 1890, the nasal cartilages began to ulcerate. At present the septum and both nasal cartilages are completely destroyed, there are large depressed oval scars all over the face and arms, and the upper lip is swollen and affected with a dry eczema, the whole face presenting a hideous appearance. In March, 1894, she had chronic periostitis of the tibia, which terminated in suppuration. The child, which was the sixth, is alive and well. A full-term child was born on Feb. 22nd, 1885; it was always ailing, had snuffles and a nasal discharge, and when fourteen months old died from marasmus. There have been no miscarriages. The patient's memory is defective, and her statements are not very trustworthy. Neither the duration of treatment nor the date of its commencement can be ascertained. The husband has apparently not contracted the malady from his wife, and there is no history of previously acquired syphilis.

CASE 6.—This patient was delivered of a child on Aug. 6th, 1882. About three weeks later she complained of noises in the ears and partial deafness. This was followed by a rash in the form of small pimples, which were first noticed on the legs, but subsequently affected the whole body, except the face and the palms of the hands. She lost her hair and had several attacks of sore-throat, with "lumps" in the neck. She has had four full-term children since 1882, without any abortion or miscarriage. The first child died from marasmus when fourteen months and a half old. The second had snuffles and a "funny head"; it died from fits and teething when eighteen months old. The third child is now four years old, and the fourth is a year and a half old. Neither of them present any signs of congenital syphilis. Specific treatment was begun two months after confinement. The patient is now fairly well, her only complaint being very marked loss of memory. The husband had a sore on the glans penis, but appears to have had very few secondary symptoms.

CASE 7.—This patient was a niece of the midwife. She is described as being the worst case of the series, and was the only primipara known to be infected. The subjoined notes are taken from her mother's statements. She was delivered of a child in August, 1882, and did not leave her bed for over three months. The vulva became very sore, and presented the appearance of raw beef. A red rash soon afterwards came out over the whole body, and ulcers showed themselves on the face. Remedies were administered from the development of the symptoms until she left home. She was then a "perfect wreck" and "horrible to look upon." Part of the upper lip and both nasal cartilages are now absent, and the face is extensively marked by scars. There have been no more children or miscarriages.

CASE 8.—This patient was delivered of a child on Sept. 12th, 1882. A vaginal examination was made by the midwife a fortnight previously, and again just before labour set in. About a month afterwards a sore appeared within the labia and was poulticed. The external organs of generation soon became raw and very tender. Rashes then appeared on the back, buttocks, and neck, and subsequently on the arms and legs. The patient was so sore that the weight of the bedclothes could not be borne, and for several weeks she could not lie down. She also had a severe and prolonged sore-throat, and "something wrong" about the anus. She lost her hair extensively. Inflammation of the eyes supervened later, but was greatly benefited by her medical attendant, who "passed needles into both eyes"; the sight is now impaired. Her memory is unaffected, and she now enjoys good health. Treatment was begun two months after delivery. The child was apparently healthy,

but contracted "small-pox" when eighteen months old, and was removed to the hospital, where it died. Two years after this labour abortion occurred at the third month without any known cause, and twelve months later a dead foetus, which was "like a bag," was born at the ninth month. Two children were subsequently born, and now seem to be quite healthy. The husband's history could not be obtained.

CASE 9.—This patient was delivered of a child in August, 1882. No trustworthy information is obtainable. The husband was inoculated and afterwards died in an asylum. The widow married again, and her residence is unknown.

CASE 10.—This patient was delivered of a child in August, 1882. It is certain that she suffered from syphilis, because she was medically examined and gave evidence in Court against the midwife. She has, however, left the district, and cannot be traced.

Remarks.—The tertiary symptoms presented by the female patients did not include any dependent on implication of the brain or spinal cord. The cranial nerves were all examined and found to be normal, except the second and, perhaps, the eighth. The senses of taste and smell were intact; there was no paralysis of the muscles of the eye-ball, and the pupils were equal and normal in every case, except the husband of the patient in Case 2, who had the Argyll Robertson pupil. There was no distinct evidence of gummatous growth in any part of the body. In Cases 1, 5, and 7 the face of the patient is extensively marked by scars resulting from the dermatitis associated with tertiary syphilis. The disease being acquired in childhood the puerperal period was continuous with the primary symptoms, hence none of the cases were treated in hospital till (in most instances) the tertiary symptoms developed. The midwife, who is still alive, knew the nature of the sore on her finger. She was tried at the Leeds Assizes in February, 1883, and was sentenced to twelve months' imprisonment with hard labour.¹

A CASE OF

RAPIDLY FATAL FACIO-CERVICAL CELLULITIS FOLLOWING TOOTHACHE.

By JAMES ELIAS, M.R.C.S. ENG., D.P.H. CAMB., &c.

ON Thursday morning, April 12th, 1894, a young man twenty years of age complained of toothache and was unable to go to his work as weigher of bluestone at a copper works. The pain was rather severe, the seat of mischief being the last right molar of the lower jaw. On the following day a slight swelling appeared on the right side of the face, the pain disappearing at the same time. By Saturday, the 14th, the swelling had increased, and in the afternoon I first saw him. On examination I found the face swollen over the right side of the lower jaw, the swelling extending under the chin and slightly down the neck. The inside of the mouth was in a state of general congestion, extending to the back of the throat, and the floor of the mouth was raised, and beneath the tongue the mucous membrane was so cedematous that it partially protruded when the mouth was open, suggesting the appearance of a second (smaller) tongue. The tooth complained of was much decayed, and sharp pain was elicited on percussing it. The temperature was 103.5° F., and the pulse 130. There had been no rigor. The offending tooth was extracted, pus welling out of the cavity. An aperient was prescribed, also an antiseptic mouth-wash. On Sunday morning (the 15th) I again saw him. The swelling in the face and neck had now considerably increased, and I felt convinced that it was a case of rapidly spreading cellulitis. I sent for Mr. Lewis of Neath to see the case with me. He came in the evening. During this short interval the disease had made rapid progress; the face appeared to be double its usual size, the right eye being almost closed. The swelling had increased all over the front of the neck, the oedema extending over the chest to the level of the nipple. The patient was at this time perfectly conscious, but he was unable to lie down, the dyspnoea, however, not being urgent. Rigor and pain were absent. Speech was difficult. The temperature was 103° and the pulse 140. We decided to operate at once. No chloroform was administered. A deep incision was made in the middle line, extending from the symphysis menti down to about the middle of the neck.

¹ The trial is reported in THE LANCET of Feb. 17th, 1883.

A probe was now carefully passed deeply amongst the structures below and parallel with the lower jaw on the right side and brought to the surface opposite the angle where the point was cut down upon. A sinus forceps was then passed along the probe, and after the latter had been extracted the forceps were opened to an extent which allowed a medium-size drainage-tube to be inserted. No pus was reached, although we probed carefully for it. The operation, which was borne well by the patient, was performed under strictly antiseptic precautions, the final dressing consisting of boracic lint (in the form of a hot fomentation) covered over with cotton wool. He passed a rather restless night, complaining of mucus at the back of the throat, which was difficult to clear away. There was no delirium, and he took nourishment fairly well. At 7 A.M. on Monday (the fourth morning after the swelling first appeared) the nurse stated that the patient had a "fit," which only lasted a few minutes, and then he died.

That this case should have ended fatally is not to be wondered at, for there were three dangers threatening the patient's life—viz., oedema glottidis, extension of phlebitis (along communicating venous branches) to the brain, and oedema of the lungs; he undoubtedly died from the first of these. The disease was evidently septic in nature and resulted from an ordinary dental abscess, so common at the roots of decaying teeth. It seems surprising that such cases as the one recorded above are not more common, and this must be attributed to the fact that the mouth, like the rest of the alimentary tract, is remarkably free from those pathogenic organisms which are the cause of septic inflammation. Such germs must, however, continually find their way into the mouth, but it is more than probable that they meet with an early death through the action of the secretions unless they find a suitable nidus, due to an abrasion of surface or faulty secretion, which would enable them to flourish. There are numbers of germs, on the other hand, mostly of a parasitic nature, which flourish well in so favourable an incubator as the oral cavity, thus proving that the oral secretions exercise a "protective influence" and exert a bactericidal action over those pathogenic microbes only which are fatal to the human organism. The exact way in which the various secretions of the human body behave towards certain bacteria offers a wide and important field for research to the practical bacteriologist; but the result of such discoveries can only tend to emphasise the importance of keeping the secretions in as healthy a state as possible and of assisting their germicidal action in all surgical operations involving mucous membrane by the constant use of antiseptics.

Neath, Glamorganshire.

A PROLONGED CASE OF HICCUGH.

By D. FERGUSON, L.R.C.P., L.R.C.S. EDIN.

THE patient was a man about thirty-three years of age, who had been suffering from hiccough for about twenty-four hours before I first saw him. He was robust and in good general health, but perhaps rather thin; he had no pain, gastric derangement, or flatulence; he did not vomit, and his bowels acted freely. His urine contained no albumen or sugar; his skin and conjunctivæ had a faint yellow tinge. Physical examination revealed no abnormality except slight hepatic enlargement. His own opinion was that there was nothing the matter with him except the hiccough. He was a total abstainer, and had been one for years. In the hope that a sudden and unexpected shock might break the habit of the spasmodic action of the diaphragm, a large piece of ice was, without previous warning, applied to his spine; but no benefit was obtained. Aromatic spirit of ammonia, ether, and pressure on the phrenics were similarly ineffectual. Thirty grains of chloral hydrate were then given, after which he immediately fell into a sleep lasting about two hours, but the hiccough continued throughout as before. Spirit of camphor was then given, followed by chloroform and tincture of opium internally, while hot fomentations with turpentine were applied to the epigastrium. No relief being obtained I injected half a grain of morphia hypodermically. At my next visit I found him decidedly worse. He looked pale, worn out, and dejected. The morphia had not produced sleep. With every spasm his whole

body shook convulsively, even the muscles of his neck quivering, and his face was for the first time slightly cyanosed. Previously he had been taking nourishment freely, but during the last few hours all food was rejected. On the administration of chloroform the hiccough ceased, but the inhalation was discontinued after a quarter of an hour on account of the shallowness of his respirations, and in less than an hour the hiccough was as bad as ever. At my next visit I was accompanied by a medical friend. No sooner had we entered the patient's room than the hiccough ceased, nor did it return during the ten minutes or so that we remained there; but it recurred with unabated severity on our departure. Probably the arrival of two medical men agitated the patient and acted on him as a temporary counter-irritant. In accordance with my friend's suggestion I endeavoured to administer tincture of belladonna in combination with aromatic spirit of ammonia; but the mere sight of the medicine produced painful retching. I therefore again injected half a grain of morphia under the skin of the arm and used chloroform inhalation. The morphia caused drowsiness, but no sleep, and although the hiccough ceased while the chloroform was being given, it returned in all its former urgency as soon as the unconsciousness passed off. The patient now seemed to be in a critical state. No nourishment of any sort had been taken for many hours, and the cyanosis was intense, while the hiccough was continuous and violent. I then sought the advice of three friends of hospital experience to whom I described the case. They recommended the successive trial, in the following order, of (1) ice to the phrenics; (2) galvanism to the same region; (3) dry cupping to the loins, on the chance that there might be latent kidney mischief; (4) drachm doses of subnitrate of bismuth; and (5) the prolonged inhalation of chloroform short of producing narcosis. It was impossible for the patient to swallow the bismuth, and the chloroform had been pushed as far as I was disposed to venture. The other recommendations were carried out, but did not produce the slightest apparent benefit. As a final resource I then injected below the skin of the arm six minims of a solution containing one-sixtieth of a grain of atropia and half a grain of morphia. The dose was large certainly, but the same quantity of morphia had been already injected without producing any further effect than a little drowsiness. In five minutes the patient was fast asleep, and the hiccough had entirely ceased. In rather less than two hours I returned, in response to an urgent summons, and found his face cyanosed, his lips particularly blue, and his breathing stertorous, and so slow and laboured that he seemed to be on the point of suffocation. There was, however, no clammy perspiration, and the pulse was comparatively strong, slow, and regular; the pupils were slightly dilated and quite insensible to light. He could not be awakened by slapping the face with wet towels, shouting into the ears, or applying galvanism to the temples, but tickling the soles of the feet made him start so violently that he regained sufficient consciousness to answer a few questions and swallow a little coffee. He was allowed to fall asleep once more, but in about an hour his breathing became so much obstructed that he was again awakened, this time with far less difficulty than before. He talked for a few minutes quite rationally, drank some beef tea, and fell asleep again. Next morning he complained of nothing except some stiffness of the neck and difficulty in swallowing. There was no return of the hiccough, which had lasted for seventy-two hours without cessation, except during the short periods while he was under chloroform and while he was visited by my medical friend and myself together. His subsequent improvement was rapid, and in a few days he regained his normal condition.

ANÆSTHESIA BY THE CHLOROFORM AND ETHER MIXTURE.

By EDGAR B. TRUMAN, M.D. ST. AND., F.I.C., F.C.S.,
PUBLIC ANALYST FOR THE BOROUGH OF NOTTINGHAM, AND SURGEON
TO THE SAMARITAN HOSPITAL FOR WOMEN, NOTTINGHAM.

THE large number of deaths from chloroform administration that has been noticed lately has caused anaesthetists to look out for a safer anaesthetic. A mixture of 1 volume of chloroform and 2 of ether has been used under the impression that the vapour inhaled would consist of 2 volumes

of ether and 1 of chloroform, and in that way the depressing action of the chloroform upon the heart would be neutralised by the stimulating action of the ether. To the chemical mind this would seem most unlikely. Ether boils at 35° C. (95° F.) and chloroform at 62·7° C. (145° F.), and it seems highly probable that the ether would vapourise out of all proportion to the chloroform. In the administering of an anaesthetic there are two factors which determine the assumption of the vaporous condition. The first of these is the property of diffusion, by which a body capable of volatilisation becomes diffused through an adjacent gas or vapour. The said body may be solid or liquid. During a hard frost it is matter of notoriety that snow will gradually disappear by evaporation. Water, in the same way, volatilises at ordinary temperatures. It is known that gases or vapours diffuse with a velocity inversely as the square root of their densities. The density of ether vapour being 37 and that of chloroform being 59·75, and their square roots 6·082 and 7·729 respectively, it follows that ether vapour will diffuse to chloroform vapour as 7·729 to 6·082, or as 100 to 78·8. So far, then, as regards diffusion, the vapour of the ether will preponderate. The second factor is the boiling point. To determine the relative proportion of the mixed vapours as occurring during the administration of the mixture I have made one or two experiments, which I will now detail.¹

Ether having a specific gravity of 0·72 and chloroform one of 1·497, two volumes of ether and one of chloroform will be very nearly of the same weight. I took equal weights—66 c.c. of chloroform and 137·2 c.c. of ether—putting the chloroform into a long, slender, stoppered vessel graduated in c.c. with a thermometer, whose volume was ascertained, as it had to be immersed in the mixed liquids. I then carefully poured in the ether, which lay above the chloroform without mixing with it. The volume then (subtracting the space occupied by the thermometer) at 18° C. was 203·2 c.c. On mixing by turning upside down a few times, the thermometer rose to 23° C., and the volume of the liquid increased. On cooling down to 18° the volume contracted down to the original volume of 203·2 c.c. I took a flask having a capacity of 1200 c.c., intending by the space thus obtained to give an opportunity for the same diffusion to take place as occurs during the administration of anaesthetics. Into this flask, which had a side tube in the neck for distillation, I introduced the mixture, closed the flask with a stopper carrying a thermometer reaching down into the centre of the flask, and connected the side tube with a glass condensing apparatus. I then placed a small water bath under the flask, and applied gentle heat. The flask was raised a little distance from the water bath, and the temperature was kept between the limits of 36·6° and 40° C. (98° and 104° F.). The heat was so gentle that the distillate came over slowly, the first 50 c.c. coming over in seventy-five minutes, the next 25 c.c. in sixty minutes, and the last 10 c.c. in twenty minutes. When these 85 c.c. had come over distillation ceased, the thermometer reading being 40° C. The specific gravity of the distillate was 0·7344. This denotes a mixture by weight of 1·87 chloroform and 98·13 ether, by volume 1·87 chloroform and 196·26 ether; in other words, 100 volumes of ether to 0·953 chloroform—i.e., less than 1 per cent. That chloroform was present in the distillate, and that its higher density was not due, or not due solely, to the alcohol which chloroform is allowed to contain, was shown by two tests: (1) formation of benzo-isonitrite by warming with alcoholic soda and phenylamine; and (2) reduction of Fehling's solution. The residue in the flask was next examined. It amounted to 103 c.c. The specific gravity was 1·187, equivalent to a mixture by weight of 60 chloroform and 40 ether, by volume 60 chloroform and 80 ether, or 100 volumes of ether to 75 of chloroform. Thus, administering this mixture, the patient would be inhaling 100 volumes of ether to 0·953 of chloroform at the first; whilst if the whole of the contents were used up the patient at the last would be inhaling 100 volumes of ether to 75 of chloroform.

¹ Since writing the above I have examined the residues left in Clover's apparatus in three administrations of the mixed anaesthetics. The specific gravities were 1·144, 1·095, and 1·028, giving the respective quantities of ether to chloroform by weight as 45·3 to 54·7, as 51·7 to 49·3, and as 59·5 to 40·5; or by volume as 90·6 to 54·7, as 103·4 to 49·34 and as 119 to 40; that is, to 100 volumes of ether, 50, 47·6, and 3, volumes of chloroform respectively, in the state of vapour. The residue first examined, as stated above, contained 100 volumes of ether to 75 of chloroform. These cases show conclusively that in administering the mixed anaesthetics we are using a vapour of varying and uncertain composition.

Consideration of these figures must show us the inadvisability of using the mixture of ether and chloroform. To be giving an inhalation which may vary between 100 to 0.9 and 100 to 75 is clearly a most dangerous proceeding. It appears to me that for ordinary cases ether is by far the safer anæsthetic of the two; that when this is contra-indicated, pure, unmixed chloroform should be used, every precaution being taken as in the case of all anæsthetics, to give it carefully; but that to use the two mixed is unscientific and unsafe. In these remarks I have had in view administration by Clover's inhaler. In giving the mixture by dropping it on to an open flannel mask the vapours would doubtless be more evenly distributed.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF TRAUMATIC INTRA-PERITONEAL HÆMORRHAGE.

By E. H. WAGSTAFF, M.R.C.S. ENG.

IN connexion with Mr. Battle's case of Intra-peritoneal Hæmorrhage in THE LANCET of Jan. 26th a sketch of the following case, which occurred recently in my practice, might be of interest.

A man met with an accident under the following circumstances. On Dec. 19th, 1893, whilst driving in an ordinary spring cart his horse stumbled and fell, whereupon he jumped from the cart and fell on the road on his left side. Assistance was immediately at hand, and he was conveyed—in a sitting position in another cart—to his home, a distance of about two miles and a half. I saw him immediately on his arrival and found that he had sustained a fracture at the junction of the middle and upper thirds of the left femur, which was promptly put into position. A careful examination was made, but no further injury could be made out. It was remarked at the time that there was an entire absence of shock. The patient was warm, and the pulse, temperature, and respiration were normal an hour after being put to bed; indeed, he was extraordinarily cheerful considering the circumstances. The friends report that, though a generally healthy man, he suffered from flatulent dyspepsia and want of appetite, evidently the result of alcoholism, his tendencies in that direction being well known. All went well until Dec. 21st, when slight vomiting set in with flatulence, the former relieving the latter. No abdominal pain was complained of. There was no dullness or undue distension of the abdomen. As the bowels had not been open since the accident an aperient was given, but without effect. The vomiting recurred at intervals until the morning of the 22nd, when it ceased, but the bowels continued obstinate. The vomiting recommenced in the early morning of the 23rd, and continued at intervals throughout the day. During the whole of this time the pulse varied between 72 and 85, and the temperature between 97.8° (after vomiting) and 99.4° F.; the tongue was moist and fairly clean, and the respiration was normal. At 8.45 P.M. on the 23rd the patient complained of faintness, and, on my visiting him at 9.30, to my surprise I found him cold, pulseless, and collapsed, in fact *in extremis*, from which condition he never rallied, but died at 10.45. The necropsy (twelve hours after death) revealed nothing of moment on first opening the abdomen. There was no peritonitis. The stomach, bowels, spleen, liver, and kidneys were healthy, the latter wonderfully so, considering the alcoholic habit. A small length of bowel above the cæcum was collapsed, but there was no undue fecal accumulation. On tracing the bowel upwards to the duodenum with a view to its removal a large retro-peritoneal hæmorrhage was discovered in connexion with the pancreas. It was impossible to define its precise origin, as the whole organ was so bruised and lacerated as to break up on handling. Here was evidently the cause of death, an accident in itself perhaps worthy of record; but I venture to suggest that the chief interest lies in the absence of any of the ordinary symptoms attending so extensive a lesion of so important an organ. The bruising

and laceration of course occurred at the time of the accident, whilst the hæmorrhage probably occurred a few hours before death as the result of inflammatory changes or the effort of vomiting.

Leighton Buzzard.

INVERSION OF UTERUS; DEATH.

By THEODORE MAXWELL, M.D. CAMB., F.R.C.S. EDIN.

THOUGH I can hardly think that cases of complete inversion of the uterus are as rare as one in 150,000, as has been stated, they are quite rare enough and fatal enough to justify my recording the following one. I find a similar case mentioned by Dr. J. L. Kerr¹ of Crawshawbooth, Manchester, where, however, the woman died ten minutes after replacement from shock and hæmorrhage, and where there was a suspicion that the midwife had pulled at the cord, which I feel sure she did not do in my case. I was called at 6 A.M. on Jan. 26th last by a midwife to a young woman in her first confinement, and found the child, which was somewhat premature, born, the woman very pale and low, and the afterbirth, which was to a large extent invested by the membranes, hanging out of the vulva. On this mass gentle traction had no effect. Pinching it near the vulva caused pain, and there was no tumour to be felt above the pubes. I then passed my finger cautiously into the vagina, and found, as I suspected, that there was no os, but that the mass was continuous with the fornix and consisted of the inverted uterus, with the placenta partly attached. I found no difficulty in peeling off the latter, and very little in replacing the uterus by the pressure of three fingers. It was, however, so soft and flabby that it could not be felt through the abdominal walls. I syringed out the vagina with a hot solution of creolin and administered a little ergotin and some egg and spirit, but death occurred in about an hour. There was no hæmorrhage at any time. The midwife said that the labour was a breech case and extremely easy, there being very little pain. The child was born about 5 o'clock, and as the afterbirth did not come and there was no pain or hæmorrhage she proceeded to wash the infant. While doing so the placental mass appeared. She had once seen a case of inversion, and had a suspicion of what had occurred and therefore sent for me at once.

Woolwich-common, Kent.

CASE OF ACUTE ALCOHOL POISONING.

By NORMAN KERR, M.D. GLASG., F.L.S.

A WOMAN aged forty-one years, wife of a labourer, a periodic inebriate, on Dec. 19th, 1894, in London, drank one and a half pints of whisky 22 over proof (47 stronger than whisky as usually retailed). As this is nearly double the ordinary retail spirituous strength, she must have swallowed more than two and three-quarter pints of the latter. The spirit was taken right off. In a few minutes she was found lying on her back insensible, and never recovered consciousness till she died five and a quarter hours later. The post-mortem appearances thirty hours after death were venous engorgement of the head, with subarachnoid effusion, in addition to old-standing congestion, with white, milk-like film on the surface of the pia mater. The walls of the heart were fatty, pale, and thickened. The cavities contained about half an ounce of fluid, tarry-like blood in the right ventricle. There was slight pleural effusion in the lungs, and patches of extravasation of blood in both. The walls of the stomach, which were thinned in parts, with patches of mucous membrane semi-detached, presented brownish-black ridges, with a red, fiery, tree-like aspect, on a translucent, pale, interspersed with red ground, corrugated inflammatory appearances extending into the duodenum. The stomach contained eight ounces of grumous fluid with a faint odour of alcohol. The spleen was engorged. The capsule of the kidneys was semi-adherent. While the patient was alive the face was pale, the eyes suffused and dull, the skin cold and clammy, with cold perspiration, the pulse thin and compressible, almost imperceptible, and the breathing stertorous. Throughout the pupils were dilated. The temperature fell 7° F. below normal.

MIDDLESEX HOSPITAL.

CANCER OF RECTUM; INGUINAL COLOTOMY; PREGNANCY; CÆSAREAN SECTION; RECOVERY.

(Under the care of Dr. WILLIAM DUNCAN.)

THERE are one or two points in this case which render it unusually interesting. The patient was young for the occurrence of such a disease as cancer of the rectum, and it is of course very rare for that disease to be complicated by pregnancy. The great difficulty which presented itself with regard to the operation of Cæsarean section was the vicinity of the artificial anus to the region of the new incision. It was imperative to render the parts aseptic before operation, in order to prevent septic infection during its progress and until the wound was soundly healed; this was effected with a most satisfactory result.

A woman aged twenty-six was admitted into the cancer ward of the Middlesex Hospital on June 28th, 1894, under the care of Mr. Hulke. Eighteen months previously she began to suffer pain on defecation, and constipation. Twelve months ago she was told she had cancer of the rectum, and for this a left inguinal colotomy had been performed. She had one child two years old. On her admission to hospital the finger encountered about one inch and a half within the anus a large firm mass about the size of an orange in the anterior wall. The mucous membrane appeared to be intact over the lower accessible portion of the tumour, but the examining finger was blood-stained. Per vaginam the mass could be felt projecting prominently along the posterior vaginal wall, but there was no ulceration of the vaginal surface. There was a blood-stained mucoid discharge from the rectum. The patient was in considerable discomfort from the irritation and straining, and injections of morphia had to be repeatedly given. In August enlargement of the abdomen and breasts led to a diagnosis of pregnancy of between five and six months' duration, but the patient could not remember when the catamenia last appeared. Owing to the extensive blocking of the pelvic canal by the malignant growth it was decided to let the patient go on to full term and then have Cæsarean section performed, for which operation the patient was transferred by Mr. Hulke to Dr. Duncan's care. The operation took place on Nov. 22nd. There were no signs of labour. The patient having been anaesthetised, the abdomen was carefully washed, and the inguinal opening into the bowel closed by a pad of lint, which was firmly supported by an assistant's hand during the whole operation. A median incision about six inches long was made and the uterus exposed. Then a large flattened-out metal Hodge's pessary was pressed on the anterior uterine wall with a view to control hæmorrhage, and the uterus was opened by a vertical incision within the pessary. It was found that the bleeding was more effectually controlled by digital compression, so the pessary was discarded. The incision cut into part of the placenta (which was attached on the anterior wall), so the wall was rapidly cut through and the opening extended chiefly downwards. The uterus was brought up to the abdominal wall by an assistant, who hooked the forefinger of each hand into either end of the incision. The membranes were ruptured and the fœtus (which lay in the first vertex position) was delivered head first. The child was a female and immediately cried lustily. The placenta and membranes were now rapidly and completely removed from the uterus, which was then brought outside the abdominal wall. The bleeding, which was not much at any time, came from vessels in the incised uterine wall. A hot sponge was put into the uterine cavity and the uterus itself surrounded by a towel wrung out of hot perchloride of mercury solution. Uterine contraction set in very soon, aided

by manipulation with the fingers and by an injection of three grains of ergotin into the gluteus muscle. A series of stout silk sutures was now passed through the uterine muscle, down to, but not through, the endometrium. Next, a large pair of cyst forceps was passed down into the vagina to make sure that the cervical canal was freely patent for the lochial discharge. The cavity of the uterus was thoroughly swabbed out with a 1 in 2000 perchloride of mercury solution, and the sutures were tied. The peritoneal edges of the uterine incision were then brought accurately together by a series of fine silk Sûnger sutures between the deep ones, and the uterus was returned to the abdominal cavity. No fluid having escaped into the peritoneal cavity during the operation, the abdominal incision was closed with silk sutures in the ordinary way. On account of the nearness of the inguinal colotomy aperture the wound was covered over with a collodion scab, and then dressed with salicylic wool and strapping. The operation lasted about one hour. On the 23rd the patient passed a restless night. Injections of morphia (half a grain) were given hypodermically every four hours, and three grains of ergotin at midnight. There was no sickness. Nutrient suppositories were ordered to be given through the colotomy wound every four hours. The pulse was 120. On the 24th she passed a better night. The pulse was steadier. An ounce of milk and the same of water were given every hour. The morphia injections were continued (two-thirds of a grain every four hours). There was very slight vaginal discharge. From this time onwards the patient progressed satisfactorily; she was continually crying out for the morphia injections, but this was due to morphia craving, for she did not appear to suffer more pain than was accounted for by the condition of the rectum. Nourishment was taken well. On the fifth day, as the breasts were causing discomfort, an aperient was given and the bowels acted well. On the sixth day fish was given and on the tenth the stitches were removed, the abdominal incision being perfectly healed. The temperature throughout never rose above 100° F. The child was thought to be little more than eight months. It weighed 5 lb. at birth, but steadily gained weight and strength whilst under observation. The patient was retransferred to the cancer wards under Mr. Hulke's care.

Remarks by Dr. DUNCAN.—It must be very rare to meet with a case such as that just described, in which a woman on whom an inguinal colotomy had been performed months previously for extensive malignant disease in the pelvis became pregnant and subsequently required Cæsarean section. When the pregnancy was first discovered after the patient had been in the hospital nearly two months it was difficult to say how far gestation had advanced, because, in the first place, the patient could remember very little about menstruation, and, secondly, the uterus was pushed up by the growth in the pelvis. It was quite evident, however, as there was so much obstruction that the proper course in the mother's interest was to let the pregnancy go on to term; but even in cases where there is much less narrowing of the parturient canal, whether from disease of the cervix uteri or of the surrounding parts, I am strongly of opinion that, provided the disease be of a malignant nature, the life of the child should receive much more consideration than if the disease were not cancerous, and an attempt ought always to be made to save it by Cæsarean section. In the present instance there was no difficulty in deciding against the induction of abortion and for Cæsarean section, and I am much indebted to the courtesy of my colleague, Mr. Hulke, for so kindly handing the case over to me for operation. With regard to the operation itself, when the abdomen was opened I did not (as has hitherto been my custom) bring the uterus outside the abdomen before incising it in order to prevent the escape of any liquor amnii or blood into the peritoneal cavity. With a good assistant it is not necessary to do this, and thus a much longer incision in the abdominal wall is avoided. Nor was any attempt made to control bleeding by constricting the cervix uteri with an elastic band; the use of an elastic band is bad, for though it stops hæmorrhage it has the grave defect of tending to cause uterine paralysis, and thus, when the constricting band is removed, violent post-partum hæmorrhage may set in. I have seen one of the most skilful operators obliged (owing to his inability to stop the hæmorrhage) to convert the Cæsarean section into a Porro operation by removing the uterus. In order to prevent bleeding during the incision of the uterus I adopted the plan recommended by Dr. Murdoch Cameron of Glasgow (and which answered perfectly in my last Cæsarean section) of placing a flattened-out

large metal Hodge's pessary on the anterior uterine wall and making a vertical incision inside the pessary whilst an assistant pressed it firmly against the uterine wall. In this case it had no effect, but that was due most likely to the fact that the placenta was situated in front. This makes my third case of Cæsarean section in which the placenta was unfortunately so placed. Now some observers say they can diagnose the placenta when in front even before the abdomen is opened. All I can say is that I am unable to do so with any degree of certainty when the uterus is exposed. In one of my former cases the anterior wall of the uterus appeared to be unusually pale, and yet it held the placenta which I cut into. If the placenta is incised the operator requires to cut through it expeditiously, taking care to let his incision extend lower down the anterior uterine wall than usual. After all, the loss of blood is not much—certainly not much greater than at an ordinary confinement. It is necessary to pass something through the cervical canal in order to ensure its patency in those cases where labour has not been started some hours previously to operating. As a rule it is better to introduce a bougie into the uterine cavity for eight or nine inches some six or eight hours previously, as the uterus is then more certain to contract after being suddenly emptied of its contents, besides which there is less danger of the lochial discharge being pent up. In the present instance, owing to the blocking of the pelvis by growth, a bougie was not inserted. The most important part of the operation is the suture of the uterine wall, and too much care cannot be taken both to avoid piercing the endometrium and to accurately coapt the uterine walls and peritoneal coats together. Silk is the material I always use and prefer. Lastly, as the patient (if recovery took place) was to return to the cancer ward, no steps (such as removal of a piece of each Fallopian tube) were taken to prevent the possibility of future impregnation. The successful result of this more than usually difficult Cæsarean section is in great measure due to the unremitting care bestowed upon it by my excellent house physician, Dr. G. Stanley Dodgson.

ROYAL INFIRMARY, NEWCASTLE-ON-TYNE

CASES OF OPERATION FOR GALL-STONES THROUGH A TRANSVERSE INCISION.

(Under the care of Dr. G. H. HUME.)

THE following report of these cases is from notes by Dr. A. M. Martin, surgical registrar.

These cases are published as illustrations of a method of operating for gall-stones which offers certain definite advantages. The first is the greater facility of access afforded by the transverse incision. Much of the difficulty of the usual operation by vertical incision arises from an insufficient exposure and inadequate access to the parts. When the peritoneal cavity is opened transversely the neighbourhood of the gall-bladder and bile-ducts is much more accessible both to the eye and the hand, and there can be no doubt that a transverse wound of the abdominal wall in this region carefully sutured heals almost as readily and with as little after-weakening as a vertical one. A further advantage of the transverse incision is efficiency of drainage. The thoroughness with which the space below the liver can be drained to a dependent opening in the right hypochondrium has been demonstrated in an able paper by Mr. Rutherford Morison;¹ and confidence in drainage with protective packing justifies the adoption of direct incision of the ducts in cases of impacted stone, in the place of more complicated and tedious methods. Where the incised duct can be sutured it is advisable to do so. After opening the gall-bladder also, the opening should be closed with sutures; but, whether sutured or not, an opened gall bladder is better left to drainage than stitched to the parietal peritoneum. It may fairly be claimed that the fatal event in the fourth case was not in any way due to the method of operating. The field of operation was found post mortem to be secluded and to be free from any appearance of sepsis. Death seemed to be attributable to cholæmia, or, at any rate, to be the result of the long-continued jaundice, whose depressing influence was in this case aggravated by mental trouble.

CASE 1.—A man aged sixty-three years was admitted into the Royal Infirmary under the care of Dr. D. Drummond in

February, 1894. He gave a history of illness beginning eight years ago with a severe attack of pain in the right side followed by jaundice. In June, 1893, he had another severe attack, and between these two dates there were many slight attacks. Some of them were ushered in by shivering. Vomiting brought relief to the pain, and each attack was followed by return or increase of jaundice. On admission he was found to be emaciated and jaundiced, and suffering from constipation and dyspeptic symptoms. On March 13th he was transferred to Dr. Hume for operation. The abdomen was opened by a transverse incision from a point outside the sheath of the right rectus to near the tip of the eleventh rib. Before the peritoneum was divided all bleeding points were carefully ligatured. The gall-bladder was found to be contracted, with thickened walls and adherent omentum. It contained no stones. After separation of some of the adhesions a large stone was found to be blocking the common duct close to the duodenum. The surrounding area having been packed with sponges, the lesser omentum was pulled forward as far as possible, and an incision made into the duct over the stone. This proved to be of very soft consistence, and it was removed piecemeal with a director and scoop. Bile flowed after its removal. A large rubber tube was placed with one end against the opening in the duct, and the other projecting from the outer extremity of the wound. Enough iodoform gauze was packed around the tube to completely isolate the area it traversed, and the operation was completed by suturing the wound in layers. The after progress of the case was as follows. There was at first a copious discharge of bile through the tube, and the wound required dressing—sometimes twice daily. The gauze was removed on the third day and the tube not till the fourth week. The discharge of bile gradually lessened and the motions had become coloured. On May 4th he left the hospital with the wound healed and the jaundice and pain entirely gone.

CASE 2.—A woman aged thirty-eight years was admitted on April 2nd, 1894. She was deeply jaundiced and stated that she had been so for eighteen months. Her first attack of pain occurred a year before her admission, when the jaundice had already existed for six months. Once the attacks of pain began they recurred at varying intervals. After each attack there were deepening of the jaundice and tenderness over the right side for a few days. It was found that she had evening pyrexia (101° F.), and hepatic dulness was increased. The gall-bladder could not be felt. She was operated upon on April 9th. The abdomen was opened by transverse incision, and the liver, enlarged and very dark in colour, presented. The gall-bladder was adherent to the great omentum. When the adhesions were separated the common duct was found to be enormously distended. The area having been guarded with sponges, the distended duct was aspirated and nine ounces of clear mucoid fluid were drawn off. As the sac was collapsing it was pulled forward and opened with scissors. Two stones were found to be blocking the opening into the duodenum, and these were removed with finger and scoop. One was an inch long and truncated at the ends; the other was smaller and faceted. A third stone was removed from the right hepatic duct at its opening into the common duct. The gall-bladder was then opened, and from it a large number of small white calculi were removed. The opening into the gall-bladder was sutured as accurately as the friability of its walls permitted. The opening into the sacculated common duct was also sutured. A large drainage-tube and gauze tampon were placed in the same manner as in the previous case. The patient made a quick recovery. The gauze was removed on the second and the tube on the thirteenth day. There was a high temperature for a few evenings. The jaundice disappeared, and the patient went out recovered on May 10th.

CASE 3.—A man aged fifty years was admitted on May 31st, 1894, under the care of Dr. Drummond and transferred to Dr. Hume for operation. He was jaundiced and had attacks of pain in the right hypochondrium, accompanied by vomiting and sweating. The operation, which took place on May 7th, consisted in opening the peritoneal cavity by transverse incision, separating adhesions between the omentum and gall-bladder, opening the latter and removing therefrom a number of small faceted calculi, as well as two large stones—one from the bladder, the other from the cystic duct. The opening in the gall-bladder was not sutured. The isolating sponges having been removed, a large drainage tube was placed—one end in contact with the gall-bladder, the other projecting from the outward extremity

¹ Brit. Med. Jour., Nov. 3rd, 1894.

of the parietal incision, and it was packed round with strips of iodoform gauze. The after-progress was uninterrupted, and the patient left the hospital recovered on June 21st.

CASE 4.—The patient was a married woman aged fifty years, who had been jaundiced for three years. The jaundice was preceded by an attack of very severe pain in the right side, accompanied by profuse perspiration and vomiting. There had been many attacks of pain, and during the three years she had every few weeks a febrile attack with vomiting and sweating, followed by deepening of the jaundice. Owing to a reverse of circumstances she had been worn down by much mental trouble as well as hard physical work. She was seen to be in an unfavourable state for operation, but she was becoming quite disabled and was anxious for relief. The operation (on June 4:h) was carried out on the same plan as in the preceding cases. The abdomen was opened by transverse incision. A large stone was found in the common duct, close to the duodenum. The duct was hooked forward with the fingers, and an incision was made over the stone, which was delivered with a scoop. It was an inch in length and flattened at the ends. The duct was not sutured, but drainage was provided for by a rubber tube and gauze packing. After the operation the patient never became quite conscious. She was restless and drowsy, vomiting now and again. She continued in this condition, with rapid pulse, slight rise of temperature (100·8° F.), and increasing drowsiness, till she died in the early morning of June 7th. The post-mortem examination of the abdomen showed that the area of the operation was completely shut off and that there was no peritonitis. The patient had apparently died from chœmia.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Causation of Agophony.

AN ordinary meeting of this society was held on Feb. 12th, the President, Mr. HUTCHINSON, being in the chair.

Dr. FREDERICK TAYLOR read a paper on the Causation of Agophony. He said that:—1. Agophony was no more than, or different from, ordinary musical *discord* or *dissonance*. 2. This discord was the result of *beats* occurring between the higher harmonics of the note uttered by the patient. 3. The beats constituting the discord were audible because the higher harmonics were reinforced while the fundamental tone and lower harmonics were suppressed. 4. Both the reinforcement and the suppression were due to modifications of the bronchial tubes, which caused them to resonate the higher harmonics and not the lower. It was pointed out that *discord* as a factor in agophony had not been sufficiently recognised by writers, and that the late Dr. Stone, in his Croonian Lectures, confined his attention almost entirely to the high pitch of the morbid sound. Discord was favoured by (1) the pre-existence of high harmonics in considerable force, such as is known to be the case with syllables containing the vowels *e* and *i*; (2) by reinforcements of the higher harmonics; and (3) by suppression of the lower harmonics and fundamental tone. The last two conditions could be effected by modifications of the resonating qualities of the bronchial tubes, such that they would resonate very high tones and would not resonate the lower normal tone. It was argued that such an alteration in the resonating qualities of the tubes was a sufficient explanation of agophony without the necessity of conceiving that liquid in the pleural cavity cut off the lower tones. It was shown that there was no ground for believing that liquid cut off lower notes and transmitted higher, or that higher notes were in general more penetrating than lower notes. It was shown, further, that the familiar sounds, such as nasal voice, the Punch and Judy voice, and others with which agophony were compared, did not depend on transmission of sound being affected by a layer of fluid, but on differences in the resonating spaces. Some remarks were then made on the position in which agophony was usually heard, with observations of twenty-one cases, from which it was shown that agophony was not always limited to the upper part of the area of dullness. The occurrence of agophony in the absence of pleural liquid was then

discussed, and a case was quoted showing its appearance in pneumonia with plugs or casts of fibrin in the bronchial tubes. The conclusion was that, though agophony was most frequent in the presence of liquid because the liquid compressed the lung, it might be produced by alterations in the bronchial tubes independently of liquid.—Dr. THEODORE WILLIAMS said he regretted that the early use of the aspirating needle nowadays had abolished the necessity of the study of certain physical signs. As regarded the nature of agophony, he supported Dr. Taylor's views, and thought it was more common in women and children than in men. One objection to those views appeared to him to be that in intra-thoracic tumour the bronchi were usually much compressed, but in no single case of this nature had he ever found agophony. Why did it last such a short time? The late Dr. C. J. B. Williams had stated that agophony would disappear whenever the fluid between the lung and the chest had accumulated to the depth of more than an inch.—Dr. MAGUIRE agreed that agophony was a sign of no practical value in medicine, and that it was merely a discordant modification of the voice due to altered conditions of resonance in the bronchial tubes. But there was a wide difference between resonance and consonance, which two seemed to be confused in the paper. Ordinary musical discord or dissonance was quite different from agophony. The harmonics of any given note uttered by a patient would never produce a discord. The nearest to it was the chord of the seventh; this was the product of the harmonics of any fundamental note, but in no sense of the word was it a discord, except in so far as it produced in the musical mind a feeling of expectancy which could only be relieved by the sequence of its "resolving chord," as it was called. Consonance could only occur with regard to one particular tone, and it was utterly impossible that a series of bronchial tubes could correspond with a consonating chamber. There was no space for such a chamber for one note, much less for all the notes of the human voice. In excessive bronchophony one got a kind of agophony, but that was an instance of resonance and not of consonance. The disagreeable noise of the phonograph was a form of agophony; it was certainly not a question of harmonics, but only of confusion of tones of different timbre but of the same pitch. The real explanation of agophony was therefore a confusion of sounds of the same character and pitch—a confused echo, tones of different quality, but not of different elevation, jarring with one another. If this were so it was impossible to conceive that Dr. Taylor's fourth proposition could be correct.—Dr. SANSOM held that agophony had still some diagnostic importance. He quoted the view endorsed by Barth and Roger that in cases of effusion, at the level at which agophony was heard, there was a thin layer of flattened lung separated from the chest wall, which was set in vibration by the voice-like the tongue of a Jew's harp. Agophony was not likely to be due to one cause in all instances.—Dr. SCHORSTEIN said that musically it was impossible to produce discord from any one note or its harmonics. In a recent case in which agophony was audible when the patient said "99" he found it to be still present when the patient sang a pure "Ah," which proved, therefore, that it could not be a discord. Dr. Taylor appeared not to have discriminated between what was musically known as discord and the popular idea of a discord—i.e., an unpleasant noise. The bleating of a sheep, the note of a bassoon, and that of a bagpipe, though unpleasant to many, were not musical discords. He remarked on the rarity of agophony in cases of recognised pleurisy.—Dr. SQUIRE stated that if, after bathing, a little water were left in the external meatus the sounds which reached the ear were altered, being raised in pitch and somewhat resembling agophony. He had recently seen a case of old-standing effusion in which agophony was plainly heard. If the explanation in the paper were correct agophony should be more frequently heard in pneumonia.—Dr. TAYLOR, in reply, said he had not been able from his reading to make out such a distinction as had been drawn between discord in its popular and in its musical senses. He relied rather on the statement made by an authority in acoustics that a compound tone might be harsh or dissonant in itself if it contained high harmonics. If the explanation quoted by Dr. Sansom held good agophony ought to be heard only along the upper line of dullness, but this was by no means the case. As intra-thoracic tumours grew from the root of the lung they early compressed the bronchi and cut off any possibility of resonance from the larynx; but he had heard a sound like agophony in a case

of malignant disease of the lung. His cases were all males with one exception, and none of them were children. Agophony could not be a pathognomonic sign of pleural effusion, and in pleuro-pneumonia it was perhaps more common than was generally believed.

The PRESIDENT notified that in future special evenings would be set apart for discussions. These would be introduced by a short and lucid account of the subject, which would then be left entirely to the meeting. At the next meeting of the society a discussion will take place upon the Affections of the Nervous System during the Early Period of Syphilis.

MEDICAL SOCIETY OF LONDON.

Unusual Maldevelopment of Skull unassociated with Cerebral Symptoms.—*High Excision of Rectum.*—*Cork in Adult Male Bladder.*—*Right Hemiplegia with Epilepsy treated by Trephining.*—*Pyloroplasty.*—*Enteroplasty.*—*Gastro-enterostomy.*—*Pseudo-hypertrophic Paralysis, with Preservation of Knee-jerks.*

A CLINICAL EVENING of the above society took place on Feb. 11th, the President, Sir WILLIAM DALBY, being in the chair.

Dr. GUTHRIE showed a boy aged four years who was the subject of typical scaphocephalus. The boat shape was present at birth; the circumference of the head was 21 in., the extreme length 8 in., and the width at the biparietal eminences 4½ in. There was synostosis of the sagittal suture, and the frontal bone was pushed forward as a whole, the keel-shaped ridge at the top being very well marked. There had been no convulsions and no rickets, and the intelligence was good. The child was the youngest of seven, three of whom had died of diphtheria, but none of the others had shown deformity of the skull. Professor Turner, in discussing the etiology of these cases, said that the synostosis was probably due to causes operating in intra-uterine life. The PRESIDENT said that he knew of a very exaggerated example of this deformity of the skull occurring in a public man of great intellectual attainments.

Mr. SWINFORD EDWARDS showed a man aged sixty-one years who was admitted into St. Mark's Hospital in February, 1891, with signs of cancer of the rectum. It extended four inches up the bowel, but he could not get his finger above it. After inguinal colotomy, a coccygeal extirpation of the rectum was performed by the method of Kraske. The patient at the present time is in good health and has had no further rectal trouble. He also said that he had operated on a second case, that of a female aged fifty years, who entered the West London Hospital in August, 1891, for rectal carcinoma. The growth measured two inches in length and extended to within three inches of the anus below; there were no extra-rectal adhesions. The patient being placed on her left side, he made an incision from the mid-sacrum to the anus, removed the coccyx, divided the left sacro-sciatic ligaments and dissected away a portion of the sacrum with the saw and cutting forceps. The growth was removed and the rectum united end to end, but this union did not hold. The patient had since much improved in health and strength. Mr. CLUTTON held that carcinomata high up in the rectum could be removed without resort to Kraske's method. He made a free incision posteriorly beside the coccyx and introduced his hand. He then opened the peritoneum freely, pulled the sigmoid flexure down, and attached it to the anal margin; he next dissected out the whole of the rectum and finally fixed the sigmoid down to the anus with many sutures. As a preliminary step it was best to perform an inguinal colotomy and introduce a plug into the lower portion of the colon to keep the wound clean. Kraske's operation would rarely or ever be required in women, but it might materially assist the operation in some cases in men. Cancer of the rectum varied much in malignancy in different subjects.

Mr. BUCKSTON BROWNE showed a man aged fifty-four years from whom he had removed a Cork from the Bladder in January, 1893. The patient was a gentleman of a sensitive habit of mind who was afflicted with occasional incontinence of urine. He was staying with a friend in the country, and in order to prevent the chance of wetting the bed he inserted into the end of his penis a small cork from an eau de

Cologne bottle. On getting up next day he failed to find the cork either in his penis or in the bed. In March, 1893, an examination of the bladder was undertaken with a negative result. In August, there being much pain after micturition and other signs of bladder irritation, he was sounded, and a foreign body was felt. Next day it was broken up with a fenestrated lithotrite and the greater portion of it removed. A week later the remaining portion came away in the eye of an evacuating catheter. The patient had remained well to the present time. The operation was done with an almost empty bladder, and he preferred this condition of the viscus for all cases of lithotrity.

Dr. OUTTERSON WOOD and Mr. COTTERELL showed two patients who had been afflicted with Right Hemiplegia and Epilepsy, who had been treated by trephining. The first patient, a female aged three years, was paralysed on the right side. When one year old she had a fall and afterwards had an epileptic seizure; several more fits followed, always beginning in the thumb and fingers. She had been trephined over the centre of the head, and there had been no return of fits since the operation. The second patient, a girl aged twelve years, had been paralysed since birth. There had been a difficult instrumental labour. There was no paralysis in other children of the same family. There was rigidity of the right hand, arm, and leg, with wasting of the leg and eversion of the foot. Epileptiform seizures commenced last April, preceded by a well-marked aura of numbness and tickling of the thumb. She was trephined over the hand centre last September, and since then there had been no fits; the hand and arm were less rigid, and she walked better. Mr. COTTERELL said that in the first case he found a cyst connected with the arachnoid, which was probably an old hæmorrhagic extravasation. In the second case the dura mater was found to be thickened, but the arachnoid and brain were healthy. He did not interfere with the exposed cerebral cortex.

Mr. HERBERT ALLINGHAM showed a patient upon whom he had performed Pyloroplasty. The man, who was thirty-four years of age, had had an acute gastric trouble four years ago, and since then signs of pyloric stricture had developed. He opened the abdomen in the middle line and explored the pylorus. Much cicatricial tissue was found round it, and so he divided the stricture longitudinally, then pulled the wound open, and stitched it across transversely.

Mr. H. ALLINGHAM also showed a woman forty-nine years of age who some years ago had complained of Dyspeptic Symptoms, and had afterwards suffered from intestinal obstruction with pain of a colicky nature. When admitted into the Great Northern Central Hospital obstruction had lasted for ten days. He opened the abdomen in the left inguinal region and found the large intestine distended with flatus. He opened the large intestine in the inguinal region. Next day, as the obstruction was unrelieved, he made a second opening over the cæcum. In the small intestine, at the junction of the jejunum with the ileum, he found a stricture, evidently the result of an old perforation. He performed enteroplasty, and later resected the artificial anus, bringing the cut ends together over a Mayo Robson's bobbin.

Mr. H. ALLINGHAM showed a third case, of a woman aged forty-one years, who suffered from severe gastric trouble some years previously. On opening the abdomen he found the pylorus involved in an enormous growth. He stitched the jejunum up to the stomach and united them over a bobbin. The operation was performed in July, 1894, and she had since gained over three stones in weight. The growth appeared to have diminished in size since the operation. Mr. BIDWELL asked if Loreta's operation was inferior to that described; it seemed to him to be simpler. For gastro-enterostomy he preferred Halstead's method of stitching. Mr. ALLINGHAM, in reply, said that pyloroplasty was the better operation for a rigid pylorus, a healthy piece of mucous membrane being inserted into the strictured portion. The bobbin acted like a splint and kept the parts firmly together.

Dr. STILL showed, for Dr. Colman, a boy aged ten years and three months who was the subject of Hypertrophic Paralysis, but in whom the knee-jerks were preserved. The weakness and enlargement commenced five years ago. There were three other children in the family, none of whom were affected. The head was curiously shaped; the mental condition was good. The muscles of the calves and the infra-spinatus muscles were markedly enlarged; the deltoids and triceps were enlarged to a less degree; and the vasti externi were enlarged and weakened more than the

interni. There was atrophy of the biceps, of the lower half of the pectoralis major, and of the latissimus dorsi. The knee-jerks, which had been very brisk, were still definitely present.

CLINICAL SOCIETY OF LONDON.

Cystic Hygroma in an Adult.—Two Cases of General Eczema and one of Psoriasis treated by Thyroid Extract.—Progressive Muscular Atrophy with Argyll-Robertson Pupils.—Two Cases of Congenital Dislocation of the Hip treated by a New Method.—Stenosis of Pharynx.—Lateral Rotation of Bodies of Vertebrae without Curvature.—Symmetrical Intermittent Parotitis with Xerostomia.—Extreme Displacement of the Heart due to Basic Cavity of Left Lung.—Green Urine due to Ingestion of Indigo.—Left-sided Empyema in a Patient who had had an Empyema on the same side Seven Years before.—Congenital Dislocation of the Shoulder backwards.

A CLINICAL MEETING of this society was held on Feb. 8th, Mr. J. W. HULKE, F.R.S., President, being in the chair.

Mr. RICKMAN GODLEE showed a case of Hygroma in an adult forty-one years of age, who when a boy had had a large swelling involving the neck, the side of the face, and the submaxillary region. This from time to time developed acute inflammation associated with pyrexia, sometimes threatening suffocation. He was first seen during such an attack in May, 1890. At that time there was a large swelling occupying the right cheek, floor of the mouth, and submaxillary region, extending part of the way down the neck and slightly to the opposite side. Part of the mass felt solid, but the greater part was obviously composed of larger and smaller cysts, some of the largest of which projected into the floor of the mouth. The tongue was covered on the upper surface with a great quantity of papillary masses, with countless minute cysts on its under surface. In November, 1890, Mr. Godlee removed through the mouth several of the large cysts, and no serious inflammation followed the operation. Since then the patient had been much more comfortable. He was again seen in November, 1894, complaining of a swelling below the zygoma, which extended over the ramus of the jaw and some distance behind it. He had taken iodide of potassium and arseniate of soda without appreciable benefit. This was, Mr. Godlee thought, an example of cystic hygroma, combined with an amount of naevoid structure. It was the first time he had met with this condition in an adult.—Mr. RUSHTON PARKER referred to similar cases which he had treated by injection, and asked what relation the naevoid growths had to lymphatic tissue.—Mr. GODLEE said the cysts communicated with one another and with lymphatics, and were lined with lymphatic epithelium. He regarded the cysts as lymphatic ravi and had removed them by wide incisions.

Dr. ALBERT WILSON showed a woman who had been suffering from Psoriasis, which gradually became general. In October last the thyroid treatment was commenced. The knees and elbows cleared first, and by the end of the year the skin was clear and supple and hair had commenced to grow. The treatment was stopped in January. There was no depression while taking fifteen grains of thyroïdin three times a day. Two cases of General Eczema which had been treated by the same method had relapsed slightly on discontinuing the extract.

Dr. JAMES TAYLOR showed a case of Progressive Muscular Atrophy with Argyll-Robertson Pupils in a young man. Weakness of the right wrist had been complained of four months before he came under observation. There was wasting of the forearms and shoulders with fibrillar twitchings. The condition of the pupil was well marked.

Mr. W. ARBUTHNOT LANE showed a boy and a girl on whom he had performed the operation of placing the head of the femur in a cavity cut in and beneath the anterior inferior spinous process of the ilium, the proximal limit of the anterior portion of the capsule being sewn firmly to the fibrous tissues about the anterior inferior spine and to the straight head of the rectus femoris at its origin, this having been cut carefully away from its attachment to the innominate bone so as to leave quite enough to make a strong retaining ligament in its new position. The thigh was rotated outwards and fixed in a suitable apparatus at an angle with the foot of about 50° or more with the vertical. At the same time movements were commenced in the acquired joint, and these soon became very free. The most important fact

was that the new articulation lay in front of the transverse axis around which the pelvis rotates—viz., a line passing through the acetabular cavities, so that instead of there being an ugly, insecure, and often incapacitating lumbar curve, with an unpleasant forward projection of the abdomen, the curve of the lumbar region was obliterated and the shortening that existed could be compensated without exaggerating the deformity, and with the result of tending to obliterate any lateral spinal curve that was previously present. It was not suggested to perform this operation in cases in which it was possible to bring the head of the femur into the acetabulum and retain it there. He had applied the same principle with the greatest possible mechanical advantage to cases of dorsal dislocation from disease of the hip joint and of ankylosis of this joint in a position of flexion.—Mr. BOWLEY considered that the first child walked very much in the same manner as if the dorsal dislocation were unreduced on one side, while the other appeared to be nearly ankylosed, with much eversion. He wished to know if any information could be afforded as to the treatment of cases of ankylosis.—Mr. F. C. WALLIS asked whether the improvement in walking noted in the boy might not be due to the raising of the foot by a high boot which had been worn since the operation. He thought the principal movement was in the pelvis rather than in the hip.—Mr. EVE referred to a case which he had treated in a somewhat similar way, making a new socket, and the head of the bone had remained in position. In another case the rim had been deficient and he had deepened the acetabulum. He recommended cutting through the great trochanter and turning it out with the muscles attached in order to gain access to the joint. He did not appreciate the advantage of advancing the head.—Mr. GODLEE doubted whether the head remained in position, inasmuch as the great trochanter appeared above the spine of the ilium.—Mr. MORGAN said the details of the operation offered many difficulties. There was great laceration of tissue and the immediate effects were severe. The result as to freedom and range of movement he did not consider a great advance on the original condition, and he was not disposed to perform the operation himself.—Mr. STANLEY BOYD had performed Hopper's operation, replacing both heads in the acetabula. Nevertheless, the child was unable to stand erect for some time afterwards, a failure he attributed to the undeveloped condition of the gluteus maximus. Later she could stand and walk. In another case, where dislocation resulted from acute effusion, one joint remained ankylosed, the opposite femur being placed in position beneath the anterior superior spine of the ilium. It lapsed into a dorsal dislocation with much eversion, but later the condition of the limb much improved.—Mr. MAKINS recounted the case of a child, who had never stood or walked, in whom he divided both femora with a successful result.—Mr. LANE said there could be no doubt of the marked improvement after operation; there was a stationary instead of a movable point of flexion, and the movements permitted were free and various. The transference of the joint in front of the axis of rotation of the pelvis was an important feature, reducing the lordosis and the difference in position of the head of the bone in the erect and supine positions.

Mr. BATTLE showed a case of Syphilitic Stenosis of the Pharynx. The patient, aged twenty-four, who had previously been under his care for tertiary ulceration of the upper part of the pharynx and gummata of the skin, developed difficulty in swallowing, with signs of commencing emphysema of the lungs, when under the care of Dr. Calvert at the Royal Free Hospital in the summer of 1894. He had been admitted for renal dropsy. The obstruction to respiration and the difficulty in swallowing were due to cicatricial contraction of the lower pharynx at the level of the tongue, the opening no larger than a No. 12 catheter, being visible when the tongue was depressed. This was surrounded by very dense cicatricial tissue, and the epiglottis had disappeared. Mr. Battle had performed a preliminary tracheotomy and then divided the stricture with scissors and a sharp knife, using dilators. The pharynx had undergone contraction for a distance of about one inch and a half, the contraction being so irregular at one point that a No. 12 could not be passed. Much improvement had resulted from the operation, but it was still necessary to employ dilatation from time to time to overcome the great tendency to renewed contraction. He referred to the rarity of these cases, and to the extreme contraction in this patient, the mouth having been almost made a closed sac, the upper part of the pharynx being shut off from

the nose in a similar manner by the earlier disease. The communication would barely admit a cedar pencil.

Mr. BATTLE also showed a girl aged ten years with a most unusual condition of the Spine, one which resembled Rotation without Lateral Curvature. She had complained of pain in the back for six months, supposed to be due to strain. There was a fulness on the left side of the lumbar spine, much more marked on stooping, which was unaccompanied by rigidity or pain. It was like a bony column, well rounded towards the left and diminishing from below upwards. On the right side there was a depression, and the muscles gave the idea of "hollow tension," there not being a normal amount of resistance to pressure. She had lost the pain and her general health had improved, but the local condition was unchanged.

Mr. BATTLE showed a third case, a very rare one, of Recurring Symmetrical Parotitis with Xerostomia. The dry mouth began five years before. The patient, a married woman aged fifty-four years, was admitted to the Royal Free Hospital under Mr. Battle's care. The parotitis had been in existence on and off for two years; its cause was unknown. The parotids were subject to an inflammatory swelling which recurred on the two sides equally about every two or four weeks. The mouth was dry and smooth, this including the tongue and the mucous membrane of the cheeks, where the glands were atrophied, as well as in the epithelial surface. She was obliged for some time to drink fluid in order to permit of mastication. She had no teeth left, using artificial ones. The parotids were considerably enlarged and firm, markedly lobular, painless, not tender, and without affection of the skin. She was a nervous woman who easily flushed on excitement and had tremors without apparent cause. The condition of xerostomia began when she was about forty-nine years old, at which age the menopause occurred rather abruptly. She improved very much when in hospital, and an interval of two months intervened for the first time between two attacks.

Dr. A. T. DAVIES showed a case of Extreme Displacement of the Heart in a female patient aged thirty-three, single, who was admitted to hospital in February, 1894, complaining of cough and occasional attacks of bleeding. On examination there was found, in addition to left apical changes, a cavity at the left base extending up to the mid-scapular region. The apex of the heart was situated anteriorly to the posterior axillary fold. She was not seen again until December, when she complained that "her heart got in the way of her arm when she moved it." Examination showed that the apex beat was then situated under the angle of the scapula, so that it had been still further drawn towards the spine, a distinct systolic thrill was felt in the upper part of the axilla, and on auscultation a loud displacement murmur was heard. There appeared to be entire subsidence of the lung symptoms.

Dr. A. GABROD showed a specimen of Green Urine sent to him from the country by Mr. Harold Owen. It was quite limpid, acid in reaction, and had a tint resembling that of green Chartreuse. It was passed early one morning by a healthy child aged two years and a half, and it transpired that on the previous evening the child had been sucking some blue cloth. The tongue was stained dark-blue. This cloth proved to be dyed with indigo. Analysis of the urine showed that the green colour was due to the combination of the yellow tint of the urine with the blue of indigo. On passing the urine through filtering paper it lost much of its green tint, and the paper was stained blue, showing that the indigo was in suspension.

Dr. S. WEST showed a lad aged fifteen who was seen at St. Bartholomew's Hospital with signs of Fluid in the Left Chest, and who gave a history of an empyema eight years previously, for which he had been operated upon. The diagnosis lay between phthisis with a thickened pleura and a second effusion, and it gave rise to much difference of opinion. A fortnight later a needle was inserted in the mid-axillary line, but no fluid escaped. As the area of dulness increased a second puncture was made later in the sixth interspace in the anterior axillary line, this time with the result of discovering pus. The next day the side was opened in the mid-axillary line and twelve ounces of pus removed. Recovery was rapid and uninterrupted and the lung re-expanded.

Mr. EVE showed an infant aged nine months delivered with instruments. The mother stated that the day after birth the left arm was noticed to be paralysed. On admission the movements of the left shoulder-joint were obviously limited, the arm being held stiffly and rigidly as oss the

chest, about opposite the nipple. A smooth spherical tumour, evidently the head of the humerus, was felt on the dorsum of the scapula, just beneath the junction of the acromion with the spine. The articular surface was directed backwards and to the right. There was half an inch shortening on the affected side. It was, he said, difficult to imagine how such a condition could be produced by injury during parturition unless the joint was malformed.

OBSTETRICAL SOCIETY OF LONDON.

Some Observations on the Temperature, Pulse, and Respiration during Labour and the Lying-in.—Annual General Meeting.

A MEETING of this society was held on Feb. 6th, G. E. HERMAN, M.B. Lond., President, being in the chair.

Dr. R. J. PROBYN-WILLIAMS and Mr. LEONARD CUTLER read a paper on Some Observations on the Temperature, Pulse, and Respiration during Labour and the Lying-in, in which they first considered the effect of labour on the temperature, pulse, and respiration. They find that their temperature results coincide with those of Dr. Giles.¹ They consider the low rate of the pulse after delivery, as given in the text-books, exaggerated. In 100 cases of normal labour observed in connexion with this point, they found that in 76 the rate was diminished, in 11 it remained stationary, and in 13 it was increased after the end of the third stage. In this series the average decrease between the rates during the first stage and half-an-hour after the end of the third was 11 beats per minute (from 89 in the first stage to 78 after delivery). Parity and the length of the labour have some influence on this fall; and after the administration of chloroform during labour it is common to find the pulse remaining high after delivery. In 19 cases of post-partum hæmorrhage there was an average rise of 19 beats per minute (78 during labour, 97 after delivery). Tension, as estimated by tracings made with Dudgeon's sphygmograph, is usually above normal during labour; but is occasionally low, notably in one case in which delivery was followed by considerable hæmorrhage. After delivery there was on the average a fall of 1 respiration per minute (23 during labour, 22 after delivery). After the administration of chloroform this decrease was not observed. They found that the average temperature of 100 cases varied between 98° and 99° F., being higher in the evening than in the morning. The highest average temperature was reached on the first day, and was higher in primiparæ than in multiparæ. Rupture of the perineum had no appreciable effect on the temperature during the puerperium. They do not agree with the statements in the text-books that the pulse is normally very slow during the first week, but found that the average rate of 100 cases was never lower than 72. The pulse-rate was faster in the morning than in the evening throughout this series. In a few cases the tension is diminished by delivery, but in the majority it is increased. Whatever may be the tension of the artery during labour, and whether it rise or fall after delivery, within twenty-four hours it has always increased so much that it is at least as great as, and generally greater than, the tension during labour. This increased tension may persist throughout the puerperium, and commonly lasts longer in multiparæ than in primiparæ. The rate of respiration was found to vary between 20 and 22 per minute. It tends to follow the pulse-rate in being higher in the morning, and not the temperature, which is higher in the evening.

The annual general meeting of the society was then held. The reports of the Hon. Treasurer (Dr. Potter), the Hon. Librarian (Dr. John Phillips), and the Chairman of the Board for the Examination of Midwives (Dr. Champneys) respectively were read and adopted, and a vote of thanks passed to each gentleman.

The PRESIDENT then delivered his valedictory address.—Dr. GERVIS proposed, and Dr. HAYES seconded, that a vote of thanks be accorded to the President for his address, and that it be published in the Society's Transactions.—This was carried unanimously.

The report of the scrutineers of the ballot was read. It was to the effect that the list recommended by the Council had been adopted, with the exception that Dr. Cullingworth

¹ Transactions of the Obstetrical Society, 1894.

was elected chairman of the Board for the Examination of Midwives.

The names of the officers have already appeared in our last week's issue. The following are members of the Council:—Dr. Thomas Rutherford Adams (Croydon), Dr. Fletcher Beach (Sidcup), Dr. Robert Boxall, Dr. Archibald Donald (Manchester), Dr. Lovell Drage (Hatfield), Dr. William John Gow, Dr. Walter S. A. Griffith, Dr. Gerald S. Harper, Dr. Constantine Holman, Dr. John D. Malcolm, Dr. David Ritchie Pearson, Dr. William Rivers Pollock, Dr. Leonard Remfry, Dr. Walter W. H. Tate, Mr. Willoughby Furner (Brighton), Mr. John Henry Salter (Kelvedon), Mr. John Bland Sutton, and Mr. James Henry Targett.

A vote of thanks to the retiring officers and other members of the Council was passed.

The following specimens were shown:—

Dr. REMFRY: Case of Absence of Uterus and Breasts.

Dr. GRIFFITH: A patient on whom Symphysiotomy had been performed.

Mr. BUTLER-SMYTHE: Pellet-like Bodies contained in an Ovarian Dermoid Cyst.

Dr. W. DUNCAN: Microcephalic Fœtus, with only one Palpebral Fissure and no Nose.

HUNTERIAN SOCIETY.

The Hunterian Oration on a Microbe of Malaria.

THE Hunterian Oration, delivered before the Hunterian Society on Wednesday, Feb. 13th, has this year been made the occasion of a most interesting and instructive exposition of one of the recent developments of symptomatology—the discovery of the microbe of malaria. It was delivered by Dr. PATRICK MANSON, who has had large experience of tropical diseases in China.

When announcing that his theme would be Malaria and its Parasite he drew attention to the vast practical importance of the subject, and deplored the inattention of English investigators to this field of research, which has been so profitably cultivated by Continental and American observers. Though malaria is rare in England, yet in India in 1879 3,500,000 persons died from fever of various descriptions, and of that number Sir Joseph Fayrer estimates that about one-half succumbed to malarial fever; that is to say, malaria is in the aggregate more destructive than tubercle, and claims six times as many victims as cholera. The specific organism of the disease was discovered by Laveran about fourteen years ago. It is polymorphic, occurring in the blood in very numerous and varied forms, most if not all of which may be classified under certain leading types: (1) free spores and free sporulating bodies, often having the outline of a diverging rosette; (2) small unpigmented epi- and intra-corpuscular bodies; (3) large pigmented intra-corpuscular bodies; (4) intra-corpuscular rosette bodies; (5) crescentic bodies; (6) various forms derived from those already mentioned; (7) flagellated bodies and free flagella; (8) bodies which are probably degenerate stages of some of those already enumerated; (9) pigmented leucocytes. These are phagocytes which have ingested the particles of pigment set free when the rosette body falls to pieces and this process of pigment inclusion can often be witnessed. All these various bodies are but different stages in the life of a sporozoön. The best explanation of their mutual relationship is that supplied by Golgi, who considers that the free spores are the first stage, and that they, invading the red blood-corpuscles and nourishing themselves on the hæmoglobin, grow into the larger pigmented intra-corpuscular forms. After a time these segment and become the rosette bodies, which presently fall to pieces and liberate spores, to start a new generation. The flagellate bodies originate either (1) from certain of the large intra-corpuscular pigmented bodies, which, having escaped from the corpuscles, after a time throw out flagella; or (2) from the crescentic bodies, which can be often seen under the microscope to change into oval and spherical bodies, and finally to throw out flagella. There are believed to be at least two leading types of the malaria organism, the benign and the malignant, differing both in their figure and in their pathological effects. The former never gives rise to the fatal pernicious fevers, but only to the mild tertians, quartans, and double tertians called quotidianas, found both in temperate and in warm climates. It

appears in the peripheral circulation in all its stages of small intra-corpuscular amoeboid body, large pigmented form, rosette, and flagellated body. The malignant forms produce the dangerous remittents, quotidianas, and tertians of warm climates. They appear in the peripheral circulation chiefly (and sometimes only) as the small epi- or intra-corpuscular non-pigmented form, and are frequently ring-shaped. The rosette, or sporulating, bodies and the pigmented intra-corpuscular bodies of the malignant type are very rarely obtained from finger blood. These stages of this type are passed in certain viscera, such as the spleen, brain, &c., and the organisms can be obtained by aspirating blood from the spleen at the beginning of a febrile rigor. The special virulence of this type seems to depend on its habit of accumulating in the viscera quite as much as on the pyrogenetic toxins which it is supposed to liberate. A principal and characteristic feature of the malignant parasite is the crescent-shaped body, a form which is usually present in the finger blood when the infection is of some standing, and especially when cachexia is marked.

Dr. Manson illustrated his description of the microbe by microscope specimens of blood from cases of typical malaria, as well as by drawings of the organisms. He also read the clinical notes of four cases of genuine tropical malaria occurring in patients under his care in the Albert Dock branch of the Seamen's Hospital, the temperature variations and the associated increase or diminution in the numbers of the microbes being represented in graphic curves. The first case was a man, stated to be forty years of age, but looking more like sixty, admitted into hospital last September. For the last five years he had been employed on steamers plying between London and Bombay. Two days after leaving Bombay on Aug. 4th, 1894, he fell ill with weakness, inability to work, excessive perspiration, and thirst, and was treated with quinine. He was not delirious and was not confined to his bed. The vessel having arrived in London he was taken to the hospital on a stretcher on Sept. 4th. On admission his temperature was 100° F., but was normal next day. His liver was somewhat enlarged, but his spleen did not apparently extend beyond the edge of the ribs. He was slightly anæmic, there was no albumen in the urine, and the thoracic viscera were healthy. He suffered from conspicuous mental aberration, apparently dementia. He was with difficulty induced to speak, and after uttering a few words he often terminated the conversation by turning his back on the questioner. At times he would get out of bed and wander about aimlessly. This demented and apyretic condition continued for about a week. On Sept. 11th his temperature was 101.6°, on the 12th it was normal, and on the 13th at 4 P.M. it was 102.2°. His apathetic, sullen demeanour, difficulty in finding words, and tendency to turn his back when spoken to recalled to Dr. Manson a case of malarial aphasia which he had seen in China many years ago, and suggested that the patient's mental symptoms might be of malarial origin and due to an accumulation of organisms in the cerebral vessels. This suspicion was at once confirmed by examination of the blood, which teemed with parasites, many being visible in every field of the microscope, and many different forms occurring simultaneously. Manifestly the patient was suffering from a mixed malarial infection, including ordinary tertian or quartan ague, as indicated by the large pigmented intra-corpuscular bodies, and in addition a malignant tertian of some duration, as indicated by the small ringed parasites and the numerous crescents. At 8 P.M. the organisms, though fewer than at 4 P.M., were still very numerous, and in seven fields twelve parasites and pigmented leucocytes were counted. On Sept. 14th the blood did not yield much additional information, but on the 15th a sporulating parasite was found for the first time, indicative of an impending paroxysm of fever. Accordingly at 2 P.M. the patient had a rigor, and at 4 P.M. enormous numbers of small epi- and intra-corpuscular unpigmented forms were discovered, showing that large numbers of spores had been liberated by the breaking up of rosette forms. No fewer than eighteen corpuscles in six fields were invaded by these bodies. On Sept. 16th at 8 A.M. fifteen parasites and two pigmented leucocytes were found in eight fields. Treatment by quinine was now commenced, and twelve hours later, after twenty grains had been taken, twenty fields yielded only nine parasites and two pigmented leucocytes. On the afternoon of Sept. 17th it required thirty-six fields to yield the same number of parasites and pigmented leucocytes, and there was no rise of temperature at the hour at which

it was due. On Sept. 13th there was a slight rise of temperature during the early morning, but only two parasites and two pigmented leucocytes were discovered in thirty-five fields. Thereafter for four days a few crescents and flagellated organisms were found, but it was evident that the parasites were rapidly disappearing. On Sept. 22nd one flagellated organism was found after examination of fifty fields, and no more were subsequently discovered. The patient's mental condition rapidly improved, coincidentally with the cessation of the fever and the disappearance of parasites from the blood, and when he left the hospital some weeks later he seemed to be in sound health both mentally and physically. This case exemplified the high practical value of examination of the blood as an aid to diagnosis. It showed also that quinine, while powerful in subduing the fever and in destroying the ordinary intra-corporal forms of the parasite, acts less promptly against the crescentic forms of the organism and the flagellated bodies derived from them. Laveran states that the flagellated bodies are among the first to disappear on the administration of quinine, but Dr. Manson's experience is to the effect that as long as crescents are seen in the blood so long will the flagellated bodies be encountered. In the present case the crescentic forms were to be detected fully a week after the first administration of quinine, and they persisted, though in diminished numbers, for a considerable time after all the other parasitic forms had disappeared. The next case was that of a man who contracted malarial fever in the West Indies and who was admitted to the hospital on Nov. 1st, 1894. He was treated by rest in bed in a warm room, liberal diet, and a gentian placebo without quinine at any time. The result was spontaneous recovery, although rigors occurred on the 2nd, 3rd, and 4th. It was interesting to observe the progressive gradual disappearance of the organisms from the blood. The flagellate organisms were found only after a long and patient search. Dr. Manson agrees with Mannaberg in the opinion that this organism is present always and in every case, although it may be in numbers so small that for days it escapes detection. In the remaining two cases microscopic examination of the blood yielded results similar to those already described.

Dr. Manson next pointed out the extreme value of examination of the blood as a means of definitely recognising the comatose, hyperpyrexial, choleraic, and other forms of paludism. He believes that many cases of so-called sunstroke or heat apoplexy are really malarial and are to be treated by prompt immersion in cold water and hypodermic injection of quinine. The portable and inexpensive pattern of microscope devised by Surgeon-Major Ross, and shown to the audience, is excellently adapted for these investigations. The routine practice of treating pyrexia in tropical diseases with quinine is an error which may be avoided by the use of the microscope, quinine being given only when the malaria microbe is present. In conclusion Dr. Manson dwelt on the ease with which the microbe may be recognised by any microscopist after a very little practical instruction, and on the difficulty in finding it experienced by those who have not had the advantage of a preliminary demonstration. He assured his hearers that plenty of cases of malaria and several other tropical diseases will be revealed by researches in the neighbourhood of the docks, and that clinical material sufficient for instruction may be obtained without much difficulty or expense. To those about to enter on practice in tropical climates Dr. Manson's address was of the highest interest.

BRIGHTON MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.—Uric Acid Gravel.

A MEETING of this society was held on Feb. 7th, Mr. VERRALL, President, being in the chair.

Dr. PALEY showed a man aged forty-four years, a turner by trade, suffering from Molluscum Contagiosum. The eruption was first noticed on the back of the neck six months ago. It has now spread beneath the chin and on to the front of the neck. There has been one vesicle on the eyelid. The patient is married, but neither wife nor child are affected.

Dr. CRESSWELL BABER showed a woman aged thirty-one years, who came to the Throat and Ear Hospital on Feb. 12th, 1894, complaining of head pain and discharge from the right ear. A large polypus, measuring nearly one

inch in length, was removed from the meatus. Afterwards a soft band was seen stretching horizontally across the fundus of the ear, which subsequently contracted till it became very narrow. On March 12th, as she still complained of pain, although less severe, she was made an in-patient. The pain was in the occipital and right temporal region and "throbbing." There was some tenderness on pressure over the right mastoid. After rest and blistering there was improvement, and the patient was discharged on March 20th, there being still some tenderness on deep pressure. Various astringent remedies were applied locally to the ear and antipyrin and other drugs administered internally. The pain was, however, so persistent as to incapacitate from work, and after consultation with Dr. Urban Pritchard it was decided to open the antrum. On Oct. 28th the antrum was opened under aseptic precautions in the usual position with a gouge and mallet. The bone was sclerosed and very dense. The antrum was not reached until the bone had been penetrated half to three-quarters of an inch. The cavity was small and did not contain pus. A probe passed into the wound touched another introduced through the meatus, but liquid did not syringe through. The wound was plugged with cyanide gauze. The patient did perfectly well, and the wound healed by Dec. 21st. The temperature never rose to 100° F. The pain was completely removed and has not returned. The ear still suppurates a little. There is now no distinct tenderness on pressure over the mastoid. Dr. Baber considered this one of the cases in which operation is demanded on account of continued pain, the result of intrinsic pressure, and which is relieved by the removal of a piece of bone.

Dr. GORDON DILL showed a man suffering from an attack of Gout in the Hand of a painless nature.

Dr. VAUGHAN HARLEY read a paper on Uric Acid Gravel, its Chemical Pathology, Symptoms, and Treatment. In a comprehensive memoir on the chemical pathology of uric acid he showed that there is no experimental evidence of its being converted into urea in the animal body, and that it is not derived from the metabolism of the general proteids which yield urea, but from the nuclein furnished by the nucleo-albumen of the tissues. After a meal, especially of animal food, the uric acid excreted rises rapidly, so that in from two to five hours the amount may be twice or thrice as much as during abstinence from food. Now it is known that a hearty meal, especially of animal food, is followed by a great increase of leucocytes in the blood, and it appears that this increase of uric acid in the urine is coincident with the destruction of the leucocytes and the liberation of their nuclei. It has been found that the uric acid excreted in leucocythæmia may be double the amount eliminated by a healthy person, the urea formation being alike in both cases. This shows that the nitrogenous matter taken as proteids in the food was equally eliminated in both cases, while the preponderance of leucocytes in one case led, by their extensive breaking-down, to a proportionate excess of uric acid. The actual seat of the formation of uric acid is still undetermined; there are some grounds for locating it in the liver. The precipitation of it in the solid form is probably due to the acid lecithin-albumen of the kidney converting disodic phosphate of alkaline reaction into monosodic phosphate of acid reaction. In the normal formation of urine the bases which combine with the lecithin-albumen are in their turn taken up by the carbonic acid generated in the tissues, and the lecithin-albumen is thereby set free for renewed action. When the blood contains a sufficiency of disodic phosphate, as in ordinary circumstances, the renal cells do not break up the soluble urates; but when the alkalinity of the blood is diminished the renal cells liberate uric acid, which is precipitated either in the tubules of the kidney, in the urinary tract, or in the voided urine, and the appearance of uric acid gravel is the result.

MIDLAND MEDICAL SOCIETY.

Exhibition of Cases.—An Unusual Form of Anæmia.

THE fifth ordinary meeting of this society was held on Feb. 6th, the President, Mr. T. F. CHAVASSE, being in the chair.

Mr. ASTLEY PROSSER showed a patient with a number of Growths in the Subcutaneous Tissue of both Arms and Thighs. The tumours, which had been noticed for nine years, were multiple, sessile, and varied in size from a pea

to a small orange. The larger masses were tender and showed some signs of inflammation. The growths were probably myxo-fibromata or fibro-lipomata.—Mr. HASLAM showed a man aged thirty-six the upper part of whose left thigh had been crushed by the passage over it of the wheels of a waggon. On admission the upper part of the thigh was bruised and there was a broad depression seen crossing the limb from just below the attachments of the adductor muscles to the pelvis, passing across the thigh below and parallel to Poupart's ligament and just missing the anterior superior iliac spine. There was no fracture of bone, but no pulsation could be felt in the femoral artery or in the posterior tibial; the limb was cold and pale. It was elevated and kept warm, the collateral circulation proving equal to maintaining its vitality. There was never any sign of impeded venous return, nor was there any amount of extravasated blood at the seat of injury, and to these two facts the successful issue of the case is to be largely attributed. The diagnosis was a rupture of the inner and middle coats of the common femoral artery. The patient is now well and able to work, and a feeble pulsation can be felt in the posterior tibial artery. The accident occurred eleven months ago.—Mr. BARLING showed a boy aged eleven who was admitted to the Birmingham General Hospital on April 14th last, with a very extensive compound depressed fracture of the right side of the head. He was deeply unconscious, and was operated on without an anæsthetic, an area of depressed bone about two inches and a half square being removed from the right side. From this a fracture ran horizontally round the forehead and was lost in the bone of the left side of the head. A large quantity of blood was liberated by stripping the dura mater from the bone of the vault of the skull. The next day it was discovered that the right arm and leg were paralysed, and to some extent the left side of the face. The boy was still unconscious and remained so for eleven days, during which time he had to be fed with a nose tube. On the twenty-first day he noticed things going on around him, shook hands when asked to do so, but with his left hand. He was unable to speak or to produce any sound except a grunt, and could not protrude his tongue; he could understand written and spoken words, and could write with his left hand. The left side of the face was still inactive, but the right arm and leg were much better. On the thirty-fourth day he spoke for the first time, saying "orange," "yes," "no," and his name very indistinctly and with a nasal twang, and it was then discovered that the soft palate was paralysed on both sides. There was now steady improvement of the paralysed parts all round, and he was discharged eight weeks after the injury practically well. The wound healed by first intention, and gave no trouble at all. At the present time the boy is emotional and easily irritated, but the only distinct remnant of his various paralyses is a slightly nasal voice.—Dr. CARTER showed a man aged twenty-nine with Complete Paralysis and Atrophy of the Deltoid, Supra-spinatus and Infra-spinatus Muscles of the Left Shoulder. Four years ago he sustained some injury of that shoulder and the adjacent part of the neck from a fall, and previously to an attack of small-pox last year the limb had not been so strong as before the injury, but no marked wasting was observed; on his recovery from the attack of small-pox, which was very severe, he found that he had lost the power of raising his left arm. Neither of the above-mentioned muscles react either to faradism or galvanism. Dr. Carter considered that the lesion was in the left anterior cornu of the cervical cord, and though directly due to the influence of small-pox might possibly have some remote connexion with the injury received four years ago.—Dr. CARTER also showed a case of Persistent Brachialgia in a man sixty years of age, supervening on an injury to, and amputation of, the third finger upwards of a year ago.—Mr. E. LUKE FREER showed a boy with Relapsed Talipes Equino-varus, which he had treated by tenotomy and manipulation and massage. The feet now showed little, if any, deformity, and the boy walked well.

Dr. DOUGLAS STANLEY then read a paper on an Unusual Form of Anæmia. The subject of the paper was that form of disease frequently called "splenic anæmia," a term which is likely to cause confusion. The cases are characterised by a marked reduction in the number of red blood-corpuscles, the white being unaltered or else also reduced. There are frequently poikilocytes and even poikiloblasts present. The hæmoglobin is also reduced. The spleen is greatly increased in size and the liver is frequently enlarged. There is no affection of the lymph glands. Marked asthenia passing into marasmus is observed, and in some cases there is pigmentation

of the skin, which may occur in local patches. The duration of the disease may extend over many years, and during its course there are acute attacks, during which the patient is greatly prostrated, may become of a yellow olive colour, and the temperature may rise to 105° F. During such an attack the urine becomes of a dark-brown red colour and contains large quantities of pathological urobilin. When such an attack passes off there is a slow restoration to the former condition. The pathological basis seems to consist in severe hæmolytic, probably due to the absorption of products from the intestine. Post mortem sclerosis of the spleen and pancreas was found, with marked changes in the supra-renals. The prognosis is always bad, although the duration may be long. The treatment which has done most good seems to be intestinal antiseptics. Extract of supra-renals (freshly prepared) produced a marked increase in the number of red blood-corpuscles.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Specimens.—Bullet Wound of the Thorax.—The Use of Increasing Doses of Bromides in Cases of Obstinate Epilepsy.

A MEETING of this society was held on Feb. 5th, Dr. ADOLPH BRONNER, Vice-President, being in the chair.

Dr. WOOD showed: 1. A Ruptured Lung. 2. The liver from a case of Suppurating Hydatids. Frequent aspiration had been practised, followed later by abdominal section (in two stages) and drainage. For six weeks all went well, the cyst draining satisfactorily. Three days before death signs of peritonitis set in. Post mortem a large cyst, containing clear fluid, was found in each lobe of the liver. The cyst which had been drained was found to be contracted. The cause of the peritonitis was doubtful. 3. Heart showing Embolus *in situ* in the Pulmonary Artery. This was taken from a woman who had her leg broken in a railway accident, there being also bruising of the femoral and tibial veins.—Mr. HORROCKS showed: 1. A Sarcoma of the Lower End of the Femur taken from a boy, amputation of the thigh having been performed. The growth was of three months' duration. 2. A Stomach showing a Perforating Gastric Ulcer.—Mr. MERCER related the early history of this case. For three years a woman had symptoms of gastric ulcer. Early one morning before taking any food a sudden attack of severe abdominal pain came on, causing the patient to swoon. Gastric perforation was diagnosed and operation decided on. Abdominal section was performed the same evening by Mr. Horrocks. A perforation of the stomach on its anterior surface near the cardiac end was found; and a fusiform piece around the perforation having been cut out with scissors the opening was closed. The peritoneal cavity was sponged out and drained. On the eleventh day the patient died from general peritonitis. The case was discussed by Drs. A. Bronner, Major, Rabagliati, and Bell, and Mr. Horrocks replied.—Dr. RABAGLIATI showed: (1) a Suppurating Ovary; and (2) an Ovary and Tube showing signs of Inflammation and Cystic Formation.

Dr. WOOD read notes of a case of Bullet Wound of the Thorax in which, although both lung and pericardium were injured, yet the patient made a good recovery. No surgical interference was attempted.

Dr. H. BRONNER related his experience in the Use of Increasing Doses of Bromides in Cases of Obstinate Epilepsy, as many as ninety grains of potassium bromide being given during the day, the dose being regulated by the frequency of the attacks. In one case the bromide produced a rash which closely simulated scarlet fever—fever, rash, and sore-throat being well marked. In another case marked loss of memory came on after the taking of bromides in large doses, requiring the medicine to be omitted. The paper was discussed by Dr. A. Bronner, Dr. Major, Mr. Wilmot, Dr. Evans, Dr. Bell, Mr. Shackleton, and Mr. Mercer, and Dr. H. Bronner replied.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

Cardiac Therapeutics.

THE fifth meeting of the seventy-fourth session of this society was held on Feb. 6th, Dr. CLOUSTON, President, being in the chair.

Professor T. R. FRASER opened a discussion on Cardiac Therapeutics with a paper on the Remedies employed in Cardiac Affections and their Indications. He emphasised the importance of the subject to the general practitioner. Having glanced at the history of digitalis and its action as a strengthener of the cardiac contractions and not as a sedative, he pointed out that many substances had been used in cardiac disability—for example, strophanthus—all of which belonged to a single group. He gave illustrative cases where in affections of the mitral valve, especially regurgitation, strophanthus had been used. Tracings showing the improvement in the pulse were shown, and the increase in the amount of urine during the exhibition of the drug was dwelt upon. In mitral and tricuspid disease, with bronchitis and emphysema, the drug had been found of great benefit. The effects of uncomplicated mitral stenosis were not so benefited by its use as incompetence. In both aortic stenosis and incompetence there was usually compensation through hypertrophy, and so the group of cardiac stimulants were not necessary. In angina opium, nitrites, or nitro-glycerine were indicated. Nitrites, however, frequently failed, sometimes where there was high tension, and sometimes succeeded where the tension was low. Iodide of potassium he could see no indication for using in cases of high tension. Its only action could be on the fibrous changes in the aorta and heart. Sometimes in aortic disease stimulants to the cardiac muscle did good. A case was narrated where from want of compensation the treatment indicated was that applicable to auriculo-ventricular disease. Under strophanthus the patient rapidly became convalescent. When cardiac degeneration came on in aortic disease and auriculo-ventricular disease appeared the cardiac tonics were indicated. Illustrative cases were given where strophanthus had proved of great value. Not only in valvular disease, but also in affections of the myocardium, this group of substances proved useful. A case was instanced where, though there was no organic valvular disease, there was dilatation and great oedema, the result of the cardiac weakness. On the exhibition of strophanthus a rapid recovery ensued. Other conditions were mentioned, for example, the cardiac weakness during fever, where tonics were indicated. Strophanthus had also been used to prevent the reaccumulation of fluid in the pleura by increasing the flow of urine. Failure should be looked for where the myocardium was so degenerated that it could not be stimulated and where the valves were so stenosed or so incompetent that compensation could under no circumstances be set up by any agent. It was claimed for strophanthus that it had been shown experimentally that it increased the cardiac contractions better than any other drug. It was entirely soluble and so was superior to digitalis, some of the active principles of which were insoluble. Again, the action of digitalis on blood-vessels was greater than its action on the heart, and hence its use was restricted as it increased the work the heart has to do. Both drugs might fail in producing diuresis from this cause, even though the action of the strophanthus on the vessel wall was but slight. The one indication for the use of cardiac tonics was cardiac insufficiency, and the practitioner should use the drug with whose action he was most familiar. Other measures of cardiac therapeutics, especially rest, were dwelt upon. Warning was given against the administration of digitalis wherever a cardiac bruit was discovered without due reference to the circumstances of the case.

Dr. G. W. BALFOUR agreed that rest and diet were well fitted to cure many cases of cardiac disease without the use of digitalis. He had been rather disappointed in the use of strophanthus, probably owing to its want of action on the blood vessels, and hence the blood-supply of the heart not being so much increased as by digitalis. He had always found the heart respond readily and regularly to due doses of digitalis. Formerly the doses used were much larger than at present. He counselled caution in the use of large doses on account of the cumulative action. If used with caution the drug could be continued for months or years. One grain every twelve hours was enough to get the tonic action, and could be continued for months or years. Where there was much oedema it was better to give large doses at short intervals to ensure rapid action; three to five or seven grains every four hours might be given with caution until diuresis set in. Evidence of saturation till thirty to forty grains had been given was seldom seen. When diuresis set in digitalis might be stopped for a few days, and when diuresis began to fall be begun again. When digitalis was given in smaller doses at frequent

intervals the action set in more gradually—differing from the copious sudden diuresis attendant on large doses. We might not notice the slowing of the pulse, and might be brought face to face with digitalis poisoning. Under those circumstances it was difficult to avoid saturation, with sickness, nausea, and rapid irregular action of the heart. Slowing of the heart was not of any great importance, and occurred early in the use of the drug. Digitalis in pretty full doses not only caused contraction, but kept the heart contracted. In all cases of heart disease we must remember that compensation was for ever failing. There was no such thing as perfect compensation. It was well to take time by the forelock and to feed the heart and tune it up, and so postpone the more serious developments. This held in all classes of cases, even in mitral stenosis. Digitalis was not always necessary, but strychnine or arsenic might be used. Where there was free regurgitation, either mitral or aortic, we should use digitalis as a tonic to the heart, but also to contract the heart and prevent dilatation. Especially was this necessary in aortic regurgitation when from the hydraulic laws which govern the circulation we had a column of blood by its weight more or less rapidly dilating the ventricle. The heart should be contracted and the urgent symptoms thus relieved. The patient must be placed in the recumbent position and relieved from pressure. Where there was obstruction in front in the shape of diseased arteries vascular stimulants must be used, or the heart may become irritable and irregular in consequence of being thrown into a state of strain. He preferred iodide of potassium because he found it efficacious. In doses of two or three grains it quieted the heart apparently because it prevented the action of digitalis on the arterioles and allowed the blood to pass more easily. Iodide was more permanent in its action than nitrites or other drugs. Iodide given in moderate doses dilated arterioles, reduced blood pressure, and allowed an aneurysm to contract. Large doses were not good. The patient was put to bed, the recumbent pulse-rate ascertained, and the iodide administered in increasing doses till the pulse-rate began to rise; we thus got the exact dose necessary to dilate the arterioles. Dr. Balfour concluded by emphasising the necessity for very careful diagnosis in cardiac conditions.

Sir T. GRAINGER STEWART found digitalis more successful than strophanthus, probably because the latter might be inferior to that used by Professor Fraser. Strophanthus was, however, better for an emergency than digitalis. It was important not to use cardiac tonics if there were active changes going on in the heart. In those cases he preferred iodide of potassium. He advocated the use of allied remedies with the cardiac tonics. In practice he attached the greatest importance to mechanical relief to the circulation by tapping pleural effusions, ascites, &c.

Dr. AFFLECK expressed his general concurrence with the statements made. Every cardiac case required treatment on its own merits; when treatment became indicated by evidence of failing compensation it was very often found that other organs had developed diseased action also. And we had to address ourselves to this state of matters, which to a large extent interfered with the application of cardiac remedies. The state of the cardiac wall, lung, kidneys, and liver became of prime importance if we were to deal effectively with the case. He preferred digitalis to strophanthus as a tonic, but found the latter useful in emergencies. He dwelt on the value of rest and diet, and the hygiene of the case. In dyspnoea dry cupping was of the greatest value, and if there was much lung engorgement moderate bleeding. In insomnia he advised the administration of equal parts of morphia and chloric ether. Speaking of the collapse which occurred in pneumonia and delirium tremens, Dr. Affleck advised the use of digitalis in large doses.

Dr. UNDERHILL spoke of the occurrence of heart trouble in children as the result either of rheumatism or of influenza, and the functional disorder of the heart in children. He spoke of the value of rest in the treatment of organic lesions, not rest for weeks, but for months or years. He advised caution in the use of opium in angina in elderly people, as the case might be gouty and complicated with gouty kidneys.

The discussion was adjourned.

SERVICES REWARDED. — Brigade-Surgeon L. Boor, M.R.C.S. Eng., of Nel. or, New Zealand, has been awarded the Imperial Volunteer officers' decoration for having served in the New Zealand Volunteer force for nearly twenty-four and a half years.

Reviews and Notices of Books.

Lo Scolgimento Storico della Fisiologia Prelezione del Professore L. LUCIANI al suo Corso di Fisiologia nella Reale Università di Roma. Torino: Ermanno Loescher. (*Historical Evolution of Physiology*. Lecture by Professor L. LUCIANI in his Course of Physiology at the Royal University of Rome. Turin: Ermanno Loescher.) 1894.

La Fisiologia in rapporto colla Chimica e colla Morfologia. Prolusione al Corso di Fisiologia Sperimentale del Dottore GIULIO FANO, Professore Ordinario nel Reale Istituto di Studi Superiori in Firenze. Torino: Ermanno Loescher. (*Physiology in its Relation to Chemistry and Morphology*. Address in the Course of Experimental Physiology, by Dr. GIULIO FANO, Ordinary Professor to the Royal Institute of Higher Studies at Florence. Turin: Ermanno Loescher.) 1894.

THESE two publications may be taken as the high-water mark of biological thought and work in Italy. They proceed from men who, in the experimental laboratory and academic chair, have already given proof of no ordinary power in research and in exposition. The first is by Dr. L. Luciani, lately chosen to succeed Professor Moleschott in the chair of Physiology at the Sapienza—an appointment received with universal satisfaction in all the schools and professional centres of Italy,—and it sustains quite worthily the high standard of scientific and literary excellence which made his predecessor's "prolusioni accademiche" famous. Starting with a "strategic map," so to speak, of the biological field, he shows how evolution within its limits has been carried out in the past and how its movements may be made still more effective for the future, laying his finger on the points which require reinforcing, and from which fresh attacks may be delivered with every prospect of success. This is done in the course of a brilliant retrospect of previous operations, in which the leaders of biological thought and work are "placed" and estimated with extraordinary precision and vividness. He is thus induced to revise many traditional views as to the respective values of these pioneers, and sets posterity right as to the exact amount of service rendered by each. For example, after commenting on the disastrous reversion of biological research into the "high priori road" by the "mechanical dynamism" of Hoffmann and the "animism" of Stahl in the last century, he indicates the salutary return to true scientific method effected by Haller, and, while giving him due credit for his work of rehabilitation, points out that the Swiss biologist's beautiful object-lessons in experimental investigation had been anticipated by the English Glisson, the real author of that doctrine of "muscular irritability" which goes by Haller's name. A healthy catholicity of appreciation pervades Professor Luciani's instructive monograph, not least conspicuous in his eloquent "apologia" for error as a contributing force in the development of biology. In a striking passage he distinguishes between "errori felici" (happy errors) and "errori funesti" (disastrous errors), and shows how even Paracelsus, with scarcely a sound indication or theory to show, had an indispensable place in biological history. Van Helmont and Silvius, amid all their waste of power and perversion of ingenuity, were also workers of good, something more than admonitory finger-posts to subsequent explorers. Borelli, again, the initiator of "animal mechanics," has been of signal use by his "errori felici," while Santorio—"that patient and acute experimentalist who lived whole days and nights suspended in a balance to determine the variations of his weight in relation to ingesta and excreta"—may be justly credited with having discovered the fact of "insensible perspiration," and must be respected as having, if

indirectly, started that complex series of investigations which have slowly built, and are still building up, the "physiology of material exchange, in which," adds Professor Luciani, "the work of the youngest and most energetic physiologists is to-day most largely employed." The whole monograph—for such it really is—is animated by the most generous belief in humanity, showing itself in an almost limitless hope. As to Italy's contribution to the "grand result," he remarks, however, in somewhat melancholy strain, on the poverty which deprives her of the "mezzi necessari" so richly furnished to the English-speaking or German investigator.

Professor Giulio Fano, as our readers are aware, was brought from the Physiological chair in the University of Genoa to fill the same post vacated by Luciani in the Istituto di Studi Superiori in Florence, and the "prolusione" under notice was delivered on entering on his new office. Choosing as his theme the relations of physiology with chemistry and morphology, he discusses in illustration the genesis and growth of the doctrine of inhibition, and reviews the work of his predecessors in that field—the brothers Weber, Schiff, Bernard, Romanes, Lauder Brunton, Hering, and others—while enlarging on the independent view already taken by himself in his "Chimismo Respiratorio negli Animali e nelle Piante." The lecture as now revised and enriched with a running bibliography is well worth perusal as the production of one who is not only a physiologist but a physiologist, and not only a physiologist but a physician.

LIBRARY TABLE.

Organic Chemistry. Part II. By W. H. PERKIN, jun., Ph.D., F.R.S., and F. STANLEY KIPPING, Ph.D., D.Sc. Lond. London and Edinburgh: W. and R. Chambers, Limited. 1895.—Despite the great number of "organic" text-books which exist we welcome the publication of the one before us, since not only are the authors well-known and valued contributors to our knowledge of organic chemistry, but they evidently possess the faculty of telling a very complex story with that simplicity and clearness which make an introductory work of real educational value. Drs. Perkin and Kipping deserve praise also for the admirable manner in which they have managed to include in the compass of two comparatively small text-books¹ so extensive a range of subjects as is presented in the enormously wide and ever-widening field of organic chemistry. Part II. (the present volume), dealing with the Aromatic Compounds, opens with an account of coal tar and its treatment, which is naturally followed by a description of the preparation and properties of benzene and the discussion of its constitution in the light of facts previously dealt with. On the subject of constitution the authors speak with evident authority and experience. When we add that the succeeding chapters include such subjects as the dyes, alkaloids (a chapter, by-the-by, which should be of service to medical students), and stereo-isomerism, it will be understood how fairly comprehensive is this account for a book which is called introductory. We do not quite understand why the book has been issued in two separate parts, since together they would have made up a volume of no bulkier dimensions than the average modern text-book, while in that form the work would certainly have been more handy and convenient.

Tables and Directions for Qualitative Chemical Analysis. By M. M. PATTISON MUIR, M.A., Fellow and Prælector of Gonville and Caius College, Cambridge. London: Longmans, Green, and Co. 1895.—This little book embodies a scheme for the qualitative chemical analysis of moderately complex mixtures of salts; its sphere of usefulness is, therefore, necessarily limited. The author admits this when he

¹ Part I. was noticed in THE LANCET, Aug. 18th, 1894.

says that "the tables do not apply to the analysis of mixtures of salts, the reactions of some of which salts are greatly modified by the presence of other salts in the mixtures, nor do they apply to very complex mixtures, nor to mixtures containing salts of the rare elements." The methods for the separation and detection of metals and acids, so far as our own experience would show, and under the conditions, of course, just laid down, are reliable and should give satisfactory results in the hands of intelligent students. It is to be observed that there is a multiplicity of similar schemes published, each of which is designed to meet the requirements of a special course of study. Their value, therefore, as with the book before us, lies within very narrow limits. Analytical work knows no limits, and analytical charts are, figuratively speaking, of little value except in well-explored seas; to the general chemist they are useless, since he is constantly meeting with rocks not marked on the map; it is better and more scientific to depend upon a sound knowledge of the principles and facts of the science, and then a clear and unobstructed course is possible.

Sell's Directory of Registered Telegraphic Addresses. London: Henry Sell. 1895.—To all men of business and to the great majority of their customers this volume is well-nigh a necessity. The extent of the field which it covers will sufficiently appear from the fact that the list of special telegraphic addresses of houses in London alone fills 295 large pages; the corresponding information for the provinces occupies nearly twice as much space. The accuracy of all these particulars is assured by their being taken from lists supplied by the authority of the Postmaster-General. Telephone numbers have now for the first time been included in the list. The National Telephone Company have officially authorised the insertion of their numbers, and those of other companies are distinguished by an explanatory word. The too-late list of additions and alterations is brought well up to date, being corrected for London to Dec. 31st, and for the provinces to Nov. 11th, 1894. A useful addition is a list of railway stations at which public telegraphic business is transacted, and maps of England, Scotland, and the Manchester Ship Canal.

James Beart Simonds: an Autobiography. London: Adlard and Son. 1894.—This little work is of the utmost interest to the veterinary profession, and in many respects deserves the attention of medical men. After a short account of his family connexions Professor Simonds describes his gaining, in 1829, the diploma of the Veterinary College, with which the whole of his subsequent distinguished career was bound up. His first opportunity for investigation of a new disease appears to have been on the occasion of the original introduction of foot-and-mouth disease into England in 1839. In 1842 he was appointed professor of cattle pathology and chief veterinary surgeon to the College, which was in 1844 incorporated by Charter as the Royal College of Veterinary Surgeons. The author describes in a most entertaining fashion the first invasions of sheep-pox, anthrax, pleuropneumonia, and cattle plague, and records with obvious satisfaction his appointment to be Principal of the College—an office which he held from 1872 to 1881, when age and ill-health induced him to retire from the official duties which he had performed so long and so worthily.

The Castle Line Atlas of South Africa. London: Donald Currie and Co. 1895.—All the sixteen maps of this series are admirably executed and coloured. Six of them are on the scale of either forty or sixty miles to the inch, whereby a great number of names of places are legibly inserted. There are also maps of Cape Town, Durban, Port Elizabeth, Pretoria, and Johannesburg—of course, on a much larger scale. The South African Republic, Matabeleland, Mashonaland, and the Witwatersrand Goldfield's are shown in much detail.

The usefulness of the atlas is greatly enhanced by about fifty preliminary pages of descriptive and historical matter.

The Phonographic Record of Clinical Teaching and Medical Science. No. 3. Edited by Dr. GOWERS and Dr. J. TAYLOR. London: Sir I. Pitman and Sons. Price 6d.—This journal, the organ of the Society of Medical Phonographers, will in future be published monthly instead of quarterly, except during the three vacation months of April, August, and September. It should prove useful in promoting the use of shorthand among medical students and practitioners, and enable them at the same time to increase the knowledge of their profession. Hitherto only medicine in its clinical aspect has been dealt with, and the present issue contains a lecture on Lateral Curvature of the Spine by Mr. Christopher Heath, and the concluding portion of Dr. Gowers' lecture on the Treatment of Infantile Paralysis; but the scope of the "Record" will be widened in later numbers. The facility for the interchange of thought which shorthand affords has long been taken advantage of by phonographers by means of what is known as the "Ever-circulator"—that is, a manuscript passing from hand to hand through the post in which is discussed some subject on which each member comments before posting to the next recipient. Each member has an opportunity of seeing the completed manuscript, and under able editorship the plan should prove especially useful to the medical student. Mr. Norman Porritt of Huddersfield, the first medical practitioner to advocate in print the use of shorthand in medicine, has undertaken the organisation of such a department of the society; and should a medical "Ever-circulator" be started Dr. Gowers has promised to contribute a series of articles on the general subject of Examination for Life Assurance. The size of the "Record" is eminently suited for the pocket and the shorthand is excellently lithographed. The admixture of elementary outlines with advanced contractions is, however, rather incongruous and not at all likely to lead to that uniformity of outline which is so desirable if use of the "winged art" is to become universal among the profession. Upon the whole the editors are to be congratulated upon the general get up of the journal of the Society of Medical Phonographers.

How to Live in Tropical Africa. By JOHN MURRAY, M.D. London: George Philip and Son.—That this book appears at a happy time no one will deny. The new field for the reception of our surplus population which has been opened up by the toils and heroism of Rhodes, Jameson, Johnson, and Stanley will probably not yield all its treasures to the colonist without some toll from the settler in addition to that which it has already exacted from its conquerors. The aim of Dr. Murray in writing this book is evidently to show that with proper attention to hygiene, a cleanly life, and the use of common sense a man may reasonably hope to either escape the dangers of tropical fevers altogether, or, at any rate, to mitigate them. The book opens with two chapters on Climatology, and the rest of it is practically taken up with the malarial problem. The precautionary measures as to sites for houses, camps, &c. are all thoroughly gone into, as well as the etiology and the recognition of the malarial parasite. Directions for treatment are given and are plainly set forth so as to be of use to the uninstructed layman. The chapters on Food, Drink, and Clothing are all excellent, and from a fair experience of rough travelling in other parts of the world we can commend Dr. Murray's unpretentious little work to all those whose lot shall lie in the fair ground of New Africa.

MEDICAL MAGISTRATE.—Mr. John V. Laverick, L.R.C.P. Lond., L.F.P.S. Glas., L.R.C.P. Edin., has been placed on the Commission of the Peace for the North Riding of Yorkshire, by virtue of his election as chairman of the district council of Hinderwell.

New Inventions.

GAITER SUPPORT FOR FLATFOOT AND TALIPES VALGUS.

THIS support is one which I have used occasionally for some years in cases of flatfoot and talipes valgus. It consists of a gaiter of black kid reaching from the tubercle of the tibia to the malleoli, and lacing in front. Running the entire length of the inner side of the gaiter, and sewn into it, is a steel bar, from one-half to three-quarters of an inch in width. To the upper part of this bar a buckle is attached; a piece of webbing passes round the ankle to the outer side, where one end is buttoned to the main band, and is continued under the hollow of the sole to the inner side, where a piece of stout black elastic is attached to it, and to the other end of the elastic a black kid strap, which is then buckled at the top of the gaiter. By this strap the elastic and webbing can be drawn up to the required pitch and altered at will. The advantages of this support are—(1) it can be fitted to any leg, and will keep its place however thin the leg may be; (2) the boots can be changed or slippers worn with-

FIG. 1.

FIG. 2.

out interfering with it; (3) it is neat, and on casual observation looks like a high French boot; and (4) in suitable cases it is very comfortable to the patient, the elastic acting as an artificial calcaneo-scapoid ligament. The cases in which it will, I think, be found specially useful are those of flatfoot combined with a valgus condition, such as we find in delicate or rachitic children. It is also useful in some older patients, but in many the surgical sole answers all requirements. Cases of valgus depending on spasm of the peronei I find do better with the inner part of the sole and heel of the boot raised, the above appliance and also the surgical sole appearing in some cases to increase the spasm. The support has been made for me by Messrs. Ferris and Co. of Bristol.

W. J. PENNY, F.R.C.S. Eng.

Clifton

NEW TRANSFUSION APPARATUS.

THE apology for introducing this new transfusion apparatus to the profession is that if ever transfusion is to become a widely used means of saving life (threatened by hæmorrhage) and alleviating the supervening distressing symptoms of certain toxic conditions of the blood—e.g., diabetes, uræmia, and certain poisons—the apparatus for its performance must be simple, compact,

and ready at hand. The many transfusion apparatus at present known to the profession, such as Professor Annandale's and Dr. Herbert Spencer's, are in themselves most excellent, but they are rarely ready at hand in an emergency, both on account of their size and complicated mechanism. A practitioner cannot be expected always to go about with a Spencer's transfusion apparatus, and should the necessity for transfusion be indicated the patient is possibly dead before the apparatus can be obtained. The advantages claimed for this apparatus by Dr. L. J. G. Carré, who suggested it, are: 1. Its absolute simplicity. Transfusion can be quite readily performed absolutely single-handed. He informs us that he has done so in a case of excessive collapse after severe post-partum hæmorrhage. 2. Its compactness. Everything that can possibly be required for the safe and successful performance of the operation is immediately at hand. 3. The small size of the complete case, so that it is possible that it may serve as one of the invariable contents of the practitioner's midwifery bag or the surgeon's operating bag. A transfusion apparatus is always required on an emergency, and generally when the practitioner is least prepared. In this apparatus he may always feel that he has with him often the last resource which will enable him to save life. Spencer's transfusion bottle is essentially a hospital apparatus, this is an apparatus rather adapted for the use of the private practitioner.

The case, which measures $2\frac{1}{2}$ in. by $3\frac{1}{2}$ in. by $7\frac{1}{2}$ in., is lined with a special leather, which will wash, so that the whole apparatus can be kept aseptic. Comprised in the case are all the instruments necessary for the performance of saline infusion—a metal-handled scalpel, a combined director and

aneurysm needle, a pair of scissors, a pair of Spencer Wells forceps, a pair of dressing forceps, and silk. The case also contains six small glass tubes, each holding a drachm of pure chloride of sodium. In addition, there is a piece of flexible celluloid funnel, attached to which is a piece of flexible rubber tube, which does not kink or collapse, this, again, ending in a glass cannula bent at an angle of 30° , bulbous at one end, over which the rubber tube fits tightly, tapering at the other, so that a vein is easily entered. The cannulas are supplied in three sizes. The apparatus is a very neat one, and should find a place amongst the instruments kept ready for emergencies in hospitals and in the midwifery bag of many practitioners. An advantage is undoubtedly possessed by having all the instruments together; the majority, however, are contained in every surgeon's dressing case, and greater call would probably be made for a small bag containing the celluloid funnel and its tubes and the chloride of sodium tubes. The apparatus is made by Messrs. C. Wright and Co., 108, New Bond-street, W.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 16, 1895.

THE reissue of a memorandum¹ on isolation hospitals by the medical officer of the Local Government Board acquires some importance by reason of a greater amplification than heretofore of the conditions under which sanitary authorities may contemplate the erection of hospitals for the reception of patients suffering from small-pox. Apart from this the memorandum has undergone but little change. Its wording has been made to meet the provisions of the legislation of last session, the document being addressed to the new district councils, and the extremely useful plans by which it is illustrated have been slightly modified, but otherwise it is essentially the same document as heretofore. The small-pox question, however, deserves attention.

On the issue some thirteen years ago of Mr. POWER'S well-known report on the diffusion of small-pox amongst the population resident around one of the small-pox hospitals of the Metropolitan Asylums Board the question of this diffusion was regarded as of such importance that a Royal Commission was appointed to inquire into the whole subject. Amongst the conclusions at which that Commission arrived we would recall the following: "That by some means or other the Asylums' hospitals, in their present shape, cause an increase of small-pox in their neighbourhoods appears to us clearly established..." and "It is evidently of paramount importance that the areas of small-pox wards, as well as their administration, should be rigorously separated from those of fever hospitals, and further that their construction should be such as to reduce within the smallest limits the chance of spreading infection."

It is, however, impossible to read that report without being convinced that the Commission were, as a body, disinclined to believe that the mischief done by small-pox hospitals was produced otherwise than by means of personal communications between the hospitals and the outside world, and their attitude in this direction endorsed the contention of a number of the witnesses who had appeared before them, notably the representatives of the Metropolitan Asylums Board. The latter body, acting on the conclusion they had maintained in this matter, soon set themselves to work in the determination to put an end to the spread of small-pox from their institutions by remodelling their administration and by laying down and enforcing regulations with a stringency and at a cost that could hardly have been effected by a body less powerful and less wealthy in the financial and other resources on which they could rely to carry out their decisions. But, unfortunately, small-pox still went on spreading around their hospitals as it had done before; and not only so, but the rate of incidence of the disease on the surrounding communities was regulated as formerly by the differing proximity of the inhabitants to the small-pox

hospitals. Taking the total results over a series of eight years beginning in 1877, and including some half dozen different periods of small-pox prevalence in London, it was found that the percentage of houses round the Fulham Small-pox Hospital in which small-pox had appeared was as follows: 30·1 within a quarter of a mile, 14·5 between a quarter and a half mile, 9·5 between a half mile and three-quarters, and 4·6 between three-quarters of a mile and one mile.

It was on the repetition of such results in the later portion of the period referred to that the Asylums Board evidently found it necessary by a series of stages to discontinue the attempt to treat small-pox in London, and the establishments down the Thames and near Dartford were the ultimate results of the decisions arrived at. And this change of procedure revealed in its results another piece of experience bearing upon the influence of small-pox hospitals, not only as diffusing infection, but of ensuring an increased frequency of small-pox epidemics by reason of the frequency of their operations in collecting together at one or more centres the occasional cases of that disease. In this way there came about a recurring concentration of the infection under circumstances that must now be regarded as often tending to the production of a poison having a special potency for spread. In fact, whereas during the sixteen years' existence in London of the Asylums Board's small-pox hospitals the death-rate for small-pox was extremely high and outbursts were frequent, it so happens that since those centres of small-pox aggregation in the metropolis have been abandoned the death-rate has been trivial in comparison with the previous one.

The experience of the last three years has tended strongly to confirm the opinion that, whatever authorities may be able to do, there are conditions under which small-pox hospitals become a distinct danger to surrounding communities. Those who concur in this view not only increase constantly in number, but they include the main bulk of investigators of repute and acknowledged standing. Some, indeed, whilst apparently accepting the conclusion, have sought to show that the distance at which diffusion of small-pox takes place is much more limited than many have supposed. Thus Dr. MATTHEWS of the Gore Farm Hospital, reporting on a single year's experience of a fever hospital, together with an asylum and schools, all of which lie about 1000 feet from a small-pox hospital, states that because no one to his knowledge contracted small-pox in any of the institutions in question "there seems sufficient evidence from this experience for assuming that the diffusion of small-pox through the air does not extend to a distance of 1000 feet." Not a word is said as to the condition of the school inmates as regards vaccination or as to the proportion of convalescents to total small-pox cases. The experience, even if vaccination and convalescence be ignored, is a solitary one, limited to a comparatively brief period; and it is negative. As such it will carry conviction to very few minds. It is also quite clear that any such view does not weigh with the authorities at Whitehall; for after a long period, in which evidence had been accumulating on the subject, they now lay down the following rules, which, though put in the form of advice, will

¹ On the Provision of Isolation Hospital Accommodation by Local Authorities, with plans. 1895. Eyre and Spottiswoode, East Harding-street, E.C.; John Menzies and Co., Edinburgh and Glasgow; Hodges, Figgis, and Co., Dublin. Price 1d.

evidently serve for the future to govern the decision of that Board in cases where their sanction is required for the erection of small-pox hospitals. "A local authority should not contemplate the erection of a small-pox hospital—1st, on any site where it would have within a quarter of a mile of it as a centre either a hospital, whether for infectious diseases or not, or a workhouse, or any similar establishment, or a population of 150-200 persons; 2nd, on any site where it would have within half a mile of it as a centre a population of 500-600 persons, whether in one or more institutions or in dwelling-houses." These conditions, it is specially stated, are laid down, not by way of indicating that the distances specified represent the limits of small-pox diffusion, or take cognisance of differing qualities of small-pox for spread in different epidemic periods, but merely "with a view of lessening the risk of infection." And a further paragraph accentuates the difficulty which is felt in attempting to lay down any general rule that shall cover all circumstances affecting different classes of communities, for it is added: "It must be understood that even where the above conditions are strictly fulfilled there may be circumstances under which the erection of a small-pox hospital should not be contemplated. Cases in which there is any considerable collection of inhabitants just beyond the half-mile zone should always call for special consideration."

Incidentally the memorandum indicates that the attempts which have been made by certain authorities to comply with the recommendation embodied in one of the conclusions of the Royal Commission we have quoted, as to reducing "within the smallest limits the chance of spreading infection" from small-pox hospitals, have not yet been successful. The complete combustion of all out-going air from such hospitals is a matter of greater difficulty than had evidently been contemplated by the Commission.

It is said by scoffers that if it were not for the unfailing variety of our weather we should have no subject of conversation. This estimate of our social weaknesses is perhaps somewhat unfair, but the fact remains that (at the present time, at any rate) the weather is the subject which is uppermost in most people's minds. We cannot wonder at this if we consider how, in a machine so highly organised as our complex modern life has become, the stoppage of one little wheel throws everything out of gear, and when we think that for eighteen consecutive nights the temperature at Greenwich has never been above freezing point, and frequently much below that point, it is easy to picture the common dangers to which this exceptionally long-continued frost may give rise.

As our household surroundings and the thousand appliances which minister to our daily life grow more and more luxurious and complicated, so we must expect any interference of the conditions under which they act to be accompanied with a proportionate amount of disturbance. Take, for instance, the supply of the first necessary of life—water. We now consider ourselves badly off if at some three separate points in a house we cannot at once command a full supply of hot and cold water by simply turning a tap. Having finished with the water we open a valve and it disappears, how or whither most

people never take the trouble to inquire. Our ancestors, who lived through winters quite as cold as the present, were naturally not nearly so much upset, inasmuch as the balance of their lives was not nearly so delicately adjusted. In the first place, they were not so particular about their ablutions, and in the second, always having been accustomed to go to the spring or the well it made very little difference whether they had to break a layer of ice or simply draw their household supplies in the ordinary way. But not only are we moderns inconvenienced, but many are practically living with what is equivalent to a charge of dynamite in the basement. It is needless here to go into the mechanism of the explosion of hot water circulating boilers, but a glance at any daily paper will show how real and how widespread is the danger. Frozen soil-pipes, again, are an obvious source of danger. The inconvenience need not be dwelt upon of having no escape for domestic sewage, but the after-effects of a prolonged block to the soil-pipes may not only be expensive of remedy, but seriously dangerous to health. As for the cold water service, we doubt not that when the thaw comes the old tale will be repeated, and flooded houses, with their accompanying evils of damp rooms, broken-down ceilings, plumbers, rheumatism, and other misfortunes, will be as common as in 1855, when LEECH drew his inimitable pictures of the heroic struggles of the BRIGGS family with the burst pipes.

Let us turn now from these effects of a frost, which, disastrous though they be, are to some extent preventable by the exercise of sense and supervision, and which, if not preventable, are endurable, to the effects upon the health of the population. A graver picture presents itself. Men must work, and women too, but it is surely a grave reflection upon a community that omnibus drivers and conductors should have to work for some sixteen hours without relief in a temperature like the present, and that no less than five have died from the cold, of whom one was found dead on his box. Upon the aged, the poor, and the very young the extreme lowness of the temperature tells most fatally, and when in addition to the cold a gale blows, any man or animal exposed without shelter runs a grave risk of death. From every part of the country, from the Channel to the north of Scotland, we hear of sailors frozen in the rigging, wayfarers lost on high roads and lonely moors; trains are snowed up with passengers and freight for days; and in one case the wild deer came down from their bleak forests and crowded among the passengers who had gathered round the engine to share in the warmth. Now it is quite evident that we cannot alter the weather, but we can mitigate its consequences by due attention to physical and physiological laws. For accidents to boilers and pipes the preventive measures to be applied are in some cases perfectly well known, and these it is the householder's fault if he does not apply. With regard to food and clothing, the two questions may be summed up in two words—fat and wool. All dwellers in cold countries consume large quantities of fat, and it is well to remember that by taking fat in some digestible shape, such as cream, butter, or small quantities of cod-liver oil, our power of resisting cold is much increased. The days have gone by when delicate women went about in the depth of winter in thin cotton

dresses with only one under-garment; but even now there is much need for the exercise of common sense in the change from morning to evening dress. Some woollen garment, however thin, should always be worn next the skin, clothing should be as loose as possible, and the fact that two thin things are warmer than one thick should be always borne in mind. If these precautions are taken those who have the means to take them may reasonably hope to come to no harm in the frost. But let us not forget the sufferings of those poor who have neither food, fire, nor clothing. The cold, so cruel to the young and the sick, is especially cruel to the under-fed; and all those of our poorer fellow-creatures whose vocations compel them to expose themselves for long hours to the bitter weather with insufficient clothing and insufficient nourishment should be made the subjects of our practical sympathy. They deserve it and require it.

ONE great difficulty in the way of hospital reform in London is the isolation of the institutions. They act apart and somewhat competitively. Each has to fight for its own hand and in its own way. Each has its own friends and is dependent to a great extent on the idiosyncrasies of its own secretary. Each has its own methods and its own views. The competition which obtains between hospitals has reference not only to appeals for help from the benevolent public, but to the number of patients attended. When the isolation of such institutions is considered, and their ever-increasing number, it will be seen how difficult it is to exercise any control over them. Their voluntary character, their peculiar glory, for the purposes of reform is apt to be even a disadvantage. For these reasons any central body with benevolent purposes which would take them all into its purview and care ought to be a great blessing, and its suggestions ought to be received with gratitude. The Charity Organisation Society therefore did good service by organising a meeting on Monday last for discussing the formation of such a board.

It is well known that such a recommendation was the principal outcome of the deliberations of the Select Committee of the House of Lords in 1889 (Lord SANDHURST's Committee), and that for some reason or other the proposal came to naught. The hospitals themselves have not welcomed the idea, and for some time past it has been in abeyance. Colonel MONTEFIORE, in the paper which he read at the meeting on Monday, gave a history of the proposal and its fate, and in an elaborate survey of the position of hospitals gave weighty reasons why in some form the suggestion should be accepted by the London hospitals. His account of the out-patient system with its 1,200,000 patients, exclusive of the casual system, (which is rapidly growing into large proportions), was almost appalling, whether we consider the interest of the patients or that of medical practitioners who begin to see in hospitals a sort of conspiracy to ruin general practice. Only the grossest abuse of hospitals on the part of the public explains why practitioners entertain such views of institutions to which they owe so much in the way of instruction. The medical speakers who took part in the discussion said nothing in depreciation of hospitals when restricted to the reception of proper cases and in proper numbers. Sir

JOHN ERICHSEN, in a dignified and thoughtful speech, touched with great judgment on the question of pay wards. He entirely disapproved of these as part of the system of an ordinary hospital. He recognised that there was a class needing the accommodation of a pay hospital, and that such hospitals or homes should be provided on ordinary commercial principles, and should in their charges meet the requirements of the clerk or other person who in emergencies might not be able to command at home the nursing and accommodation necessary for his case. Though the monstrous proportions of the out-patient department and the tendency to adopt the pay system were the principal evils dwelt on by the speakers on Monday, it was not denied that there were others—that some medical charities are excessive in their cost, that in-patients are admitted who can well afford to pay, and that the system of accounts is far from uniform. Colonel MONTEFIORE did not speak pessimistically of the finances of hospitals; but he showed the extreme uncertainty of legacies as a means of income, while it is on them that hospitals seem to depend more than they do on annual subscriptions. Moreover, legacies are bequeathed with so little system and so capriciously as to enrich some hospitals and leave others impecunious.

The promoters of the meeting were probably well advised in being content with a general discussion and in not pressing conclusions to the length of a resolution in favour of a central board. This was done out of consideration to hospital authorities, and wisely done. But these authorities on their part will do well to take note of this meeting as an index of growing public opinion in favour, not only of the retention of voluntary hospitals, but also of their being restricted to the relief of persons gravely affected with disease and unable to command medical advice and comforts proportionate to their need. The creation of a central board would in no way injure well-conducted hospitals. The chairman of one hospital and the chairman of the Hospital Saturday Fund thought there would be difficulty in defining the duties and functions of such a board. But it will be to the discredit of the able and experienced business men who administer our hospitals if they cannot agree on some general functions—friendly and advisory—which would tend to support our much-threatened hospital system.

Annotations.

"Ne quid nimis."

THE DUKE OF CONNAUGHT ON ST. THOMAS'S HOSPITAL.

PRACTISED orators to a certain extent all of our Royal Family tend to become, but it required more than verbal facility to speak as sympathetically and as accurately as His Royal Highness the Duke of Connaught did at the Mansion House on Wednesday last, when appealing to the public for £100,000 to place St. Thomas's Hospital, of which institution His Royal Highness is the president, on a securer financial basis. It required an intimate acquaintance with the subject and a deep sympathy with the needs of the suffering poor to speak at once so broadly and so precisely, and we cannot doubt that the practical outcome of the appeal will be substantial, although—to put it colloquially—

times are very hard. During the whole of the period the opportunities that the institution has of doing good have been seriously crippled by a lack of funds, and the authorities now find themselves face to face with the following crucial question: How best can they help the sick of an enormously increasing neighbourhood when their own funds compel them to offer a rapidly decreasing accommodation. For there can be no doubt that if substantial aid is not forthcoming yet more wards will have to be closed. His Royal Highness pointed out that it was through no fault of the hospital authorities that their expenditure had grown while their income had dropped. The vast spread of South London threw an ever acuter strain upon their resources, while agricultural depression lessened their income, both directly by depreciating the hospital property and indirectly by affecting their subscription list. Many and many wide and vexed questions in hospital constitution and hospital administration in the metropolis were touched upon, to which we do not at the present moment intend to make reference, considering that we shall most efficaciously back His Royal Highness's appeal by simply summing up the immediate situation. St. Thomas's Hospital is allowed on all hands to be doing splendid charitable work, and it cannot continue to do so unless the public will come to its immediate rescue. This we hope earnestly they will do, and in such a bountiful manner that this great charity will be able to pursue its beneficent life, and, by closing its pay wards, pursue it on proper lines—those of pure and undefiled charity.

THE PATHOLOGY OF PNEUMONIA.

FACT and hypothesis were happily blended in the communications made at the last meeting of the Pathological Society by Dr. Washbourn and Dr. Wright bearing on the pathology of acute lobar pneumonia. Dr. Washbourn rigidly confined himself to observations upon the microbe that has been proved to be the almost constant concomitant of this disease; whilst Dr. Wright, in his suggestive reasonings from analogy, put forward sundry explanations of the remarkable phenomena that characterise it. The bacteriological history of acute pneumonia is instructive, since in the first instance the bacillus discovered by Friedländer was thought to be—and the view received support from many sides—the pathogenic organism responsible for exciting it. But Dr. Washbourn's statement that the real "pneumococcus" is that discovered by Fraenkel and Talamon, and studied by Sternberg and Weichselbaum and many others, is in accord with general opinion, although we note in a recently published text-book of high standing in this country the pneumonic rôle is still assigned to the bacillus of Friedländer. Dr. Washbourn pointed out that the occurrence of the pneumococcus in healthy secretions did not militate against its pathogenic property, instancing diphtheria as an example of this. Now although practically the same conclusion was arrived at some years ago by Dr. Sternberg, it must be admitted that the fact enlarges the view of the microbic origin of disease. It seems to demand the intervention of a second factor, disposing the body to the action of the organisms. Indeed, for pneumonia such a factor has been assumed in the phrase "lowered vital resistance," such as may be produced by cold or exhaustion, rendering the subject more vulnerable. Experimentation upon animals with regard to the pneumococcus has brought out many interesting facts as proving its relation to inflammatory processes in various tissues and organs; but it cannot fail to strike the clinical observer that the parts mostly attacked by inflammation after "pneumococcal" inoculation are not those which are prone to such lesion in the human disease. This was partly

explained by Dr. Wright's statement that the pneumococcus had mainly a local action, and in acute pneumonia its entrance is obviously by the respiratory tract. The question of immunity and the allied subject of the use of "curative serum" has been studied experimentally in pneumococcus infection for some time, notably by Drs. G. and F. Klemperer of Munich; indeed, some of the earliest work on "antitoxins" was that done on the occasion in question by these observers. It is clear, however, that more requires to be proved before the practical application of such researches can be adopted. Moreover, in a self-limited disease like pneumonia it will be assuredly a difficult matter to determine whether the abatement of symptoms is due to the administration of serum from an immunised subject—e.g., the blister serum from one who has just passed through an attack—or to the natural termination of the process. Amongst the striking phenomena of this remarkable disease must be reckoned the occurrence of crisis and the reabsorption of the mass of exuded leucocytes, which convert the spongy tissue into a solid grey mass. Dr. Wright advanced an interesting explanation of the crisis when he compared it with the phenomena of spirillum fever. Crisis is denoted by a rapid fall in the excessive leucocytosis that precedes it, and this means the withdrawal of pneumococci from the blood; yet neither the height of the fever nor the degree of crisis is influenced by the amount of lung involved—i.e., of leucocytal emigration from the blood; nor do signs of resolution concur with those striking changes in the functions of the whole body which supervene at the crisis; nor finally, as Dr. Washbourn says, do the pneumococci exist to any marked extent in the blood. That the reabsorption—sometimes with great rapidity—of the large amount of nucleo-albumen of which exuded leucocytes are composed does not lead to intra-vascular thrombosis, in accordance with the late Dr. Wooldridge's beautiful demonstration, is remarkable, and was explained by Dr. Wright by assuming an equally rapid elimination by the urine, and in some cases, perhaps, by the bowels, of the absorbed material. It is well known, however, that the periods of crisis and that of commencing resolution are often those at which the need for free stimulation is most urgent; and we are far from saying that some of the deaths at this period of the disease attributed to cardiac failure may not really be due to cardiac thrombosis. On either view alcohol is indicated, and we may add that ammonia, another time-honoured remedy, would equally answer the indications, and that most physicians would rather trust to it than to citric acid to prevent the tendency to coagulation within the blood-vessels.

LIFE ASSURANCE SCHEMES.

Two life assurance schemes have been recently pressed upon public notice, one devised by an American the other by an English company, being the Mutual Life Assurance Company of New York and the Royal Exchange Assurance Company respectively. Of the ability of both companies to meet their obligations it is possible to speak with a large measure of confidence, for each is prudently managed and possessed of ample means. In this respect there is no need to choose between them. But the two plans are very distinct in character, and we cannot hesitate to give the preference from a professional point of view to the English scheme. The object of its originators has been to give as large an immediate return as possible upon the premium charged, and for this purpose the distant future is sacrificed to the near. That is to say, the Royal Exchange Company is prepared to issue policies at extraordinarily low rates of premium upon the condition that the remitted balance of the ordinary premium rate shall be represented by an accumulating debt chargeable against the policy monies when these fall due for payment. This growing debt

may probably have the effect of cancelling the assurance in the case of persons who live to extreme old age, so that the transaction really works out to a temporary assurance covering the working life-time, and the premium rate is proportionately light. The American scheme, on the other hand, reverses this process. During the first twenty years of what is—not very felicitously—called a debenture policy, part benefit only is enjoyed and even when death occurs one-half only of the sum assured becomes payable, the payment of the other half being deferred for twenty years upon payment in the interval by the company of interest upon the withheld balance at the rate of 5 per cent. Thus, in the English scheme the idea of life assurance properly so called prevails; in the American the prevailing idea is that of an investment. We have on previous occasions expressed the opinion that what a medical man needs to compass by means of a life assurance policy is mainly a protection to his dependents against the pecuniary consequences of his own premature decease. It is a grievous mistake to be led away by the prospect of personal advantage in the distant future from making the largest possible provision for the contingencies of the near future. We think, therefore, that medical men contemplating life assurance will do better to examine the Royal Exchange Company's prospectus than that put forward by the Mutual Assurance Company of New York, for the former is conceived in the spirit of a juster appreciation of what the assurer requires. The latter is eminently well adapted to produce a large accumulation of funds in the hands of the company's trustees, but that is an object in which the company's policy holders cannot be expected to take a very lively interest.

THE TEETH OF SIOUX INDIANS.

A RECENT pamphlet by Dr. Wilberforce Smith contains some interesting data relative to the teeth of ten Sioux Indians which he had the opportunity of examining at the time of the visit of the "Wild West" to London. The manner of investigation pursued by him was to count the teeth in pairs—for instance, the first permanent lower molar and its opposing tooth, the first permanent upper molar, would be considered one pair; when applied to the whole of the molar and premolar series the number of pairs would be ten (six molar and four premolar). Basing his observations upon this method he found that in five of the Indians under the age of twenty-two two had the pairs complete, the remaining three being two pairs short, due to the fact that the third molars had not erupted. Of five Indians between the ages of thirty-five and fifty, four had the pairs complete, the remaining one having two pairs missing due to the absence of the third molars. By way of contrast Dr. Wilberforce Smith records some observations upon the teeth of the average Londoner. In nineteen cases between the ages of twenty and twenty-one the number of pairs was found to be reduced to 2.50 in the molar series and to 2.53 in the premolar; while in twenty-two cases between the advanced ages the number of pairs was reduced to 1.12 in the molar region, the statistics of the premolar region not being recorded.

L'UNION MÉDICALE.

OUR admirable contemporary, *L'Union Médicale*, has inaugurated its entrance on fifty years of uninterrupted existence by some rather startling changes. For the future it will appear once a week only, instead of three times as formerly; but, on the other hand, although the number of pages of letterpress (twelve) remains the same the size is almost doubled, and there is a vast improvement, not only as regards type, but also in the quality of the paper used. The price, which used to be thirty-two francs per annum, making *L'Union Médicale* the most costly of all the Parisian medical

journals, now becomes five francs, which certainly seems extremely moderate, as it brings the charge for a single copy down to something less than a penny. In the course of some remarks addressed to his readers before the transformation the Director, Professor L. G. Richelot, says: "The alterations which time has wrought in our scientific and professional habits have profoundly modified the material conditions of journalism as well as of its aspirations and tendencies. We no longer write with the same ink, we no longer chat in the same way with our readers, we are colder and more formal, less prone to discussion, criticism has given place to reporting à outrance, to ill-digested news." Professor Richelot nevertheless concludes that it is necessary to march with the times. "*L'Union Médicale* wishes to follow contemporaneous progress without, however, blindly obeying the mode," and hence the modifications in form and price. Considerable changes have also taken place in the editing department. Dr. H. Richardiére is associated with Professor Richelot as director of the medical section of the journal. Each number is to contain a leading article dealing in turn with every branch of the profession. The reports of scientific societies are, it is stated, to be placed before the reader in a form that will prove attractive instead of after the usual out-and-dried fashion. All questions concerning the dignity and the interests of medicine will, as heretofore, continue to be defended; and any work, French or foreign, which may possess real value will be thoroughly criticised and done justice to. The ardent desire of the direction is to evolve genuine medical journalism; to set forth facts scientifically and critically, but entirely in their own language and from their own point of view; and to, as far as possible, avoid producing pages of stenographic reportage bearing a close resemblance to an index catalogue. A bi-monthly *feuilleton* will still be a feature of the rejuvenated journal, and a review of hygienic affairs will, as usual, be entrusted to the competent hands of M. Jules Rochard. The responsible, but not easily defined, duties of *rédauteur-en-chef* continue to be performed by M. Eugène Rochard, who has occupied the post for the last two years. In conclusion, the Direction address a pious souvenir to the original founders: Amédée Latour, Richelot, and Aubert Roche, in whose footsteps they hope to tread.

"DANGERS IN THE POCKET."

IN THE LANCET of Jan. 26th we published a brief note on the dangers likely to be incurred by carrying certain articles of popular request in the same pocket. The details of the particular case to which we referred have since been reported to us by Dr. W. Davidson, and we are glad to note that the result of the "pocket explosion" has not been so serious as it might have been. On the morning of Saturday, Jan. 19th, Dr. Davidson was called to see the patient and found him suffering from an extensive burn of the inner surface of the left thigh, with another burn of smaller extent, but more severe, extending over the thenar half of the left palm. The history of the injury elicited was that the patient had been suffering from sore-throat and had purchased some chlorate of potash lozenges. These he was carrying in his trousers pocket rolled up in a piece of paper. One of the lozenges was loose in the pocket, which also contained a box of safety matches. While moving about he suddenly heard a noise like the hissing of a squib before the detonation, and saw smoke issuing from his pocket, which he grasped from the outside thinking to smother the fire. An explosion followed which blew out the whole of the front of the trousers-leg. There was no loud noise, only an exaggeration of the hissing noise heard at first, but there was a considerable volume of flame. What had evidently happened was that the loose lozenge, by rubbing on the composition on the outside of the box of safety matches, had become ignited and that the rest of the lozenges had been exploded by it, causing

the chief explosion. On the room being searched the remains of several of the lozenges were found. They had been reduced to about a third of their normal size and the outside of them appeared scorched. The patient had fully one ounce of the lozenges in his pocket at the time of the occurrence. On Jan. 25th the wounds were healing rapidly and were almost entirely covered with new epidermis.

THE PAY SYSTEM AT THE GREAT NORTHERN CENTRAL HOSPITAL.

WE understand that Dr. Glover has given notice of the following motion for consideration at the annual meeting of the governors of the Great Northern Central Hospital on Friday, Feb. 22nd, at 5 P.M.:—"That this meeting of governors of the Great Northern Central Hospital regrets the recent changes in the administration of the hospital by which pay patients have been admitted to its wards, to be attended gratuitously by the honorary staff, is of opinion that such a system is not likely to conduce to the welfare of the hospital or the advantage of the poor for whom such institutions exist, and should without further delay be abandoned."

FROZEN WATERCLOSETS.

THE discomforts, not to say dangers, which attend the freezing of water-pipes are alone hard enough to endure; but when the frost is so severe and stays so long with us as to lead to the stoppage of soil-pipes we are brought face to face with a new evil which demands very prompt and careful action. We learn that in many houses in the suburbs of London this has occurred, and that in many cases the occupiers have been obliged to carry the excreta into the garden or to avail themselves of the premises of an obliging and more fortunate neighbour. When the thaw does set in the consequence of this condition of things may be very serious, and those who are unfortunate enough to be in such an unenviable position should have a stock of some efficient disinfectant at hand. It would be a proper and useful preliminary precaution to place a quantity of disinfecting liquid, such as carbolic acid, in the pan of the frozen closet. The public health authorities might, we suggest, help the people in this matter, so that pestilence and disease may not be counted amongst the contingencies which prolonged frost brings in its train.

LIFEBOAT EFFICIENCY.

FROM time to time we have directed attention to the work which has been carried on by the National Lifeboat Institution with so much unselfish heroism, and, happily, with no small measure of success, during the past seventy years. Every winter, every storm, adds to the lustre of a record which our spoken praise may explain, but cannot glorify. Lives have, indeed, been saved around our coasts by other more or less efficient agencies; to all such we would allow due honour; nor is the Institution already mentioned less free in its commendation of these allies. Nevertheless, with all our admiration of the gallant disregard of danger shown by fishermen and others engaged in this generous duty, we cannot but associate the work of rescue with a system which has been above all other agencies distinguished in it. Of course, there is no organisation which is perfect, and the Lifeboat Institution is doubtless governed by this general rule. Its boats, we are told, are constructed on antiquated and even dangerous models; they owe their utility largely to the aid of steam-tugs, and much of the fame commonly associated with their use must be accorded to the rocket apparatus. All this is partly true; but still the fact remains that neither steam-tug nor rocket gear can, except under certain conditions, be enabled to reach and to save the living freight of

shipwrecked vessels. This is, in fact, the peculiar faculty of an efficient boat service. Whether more might not be done than is now done to increase the present degree of efficiency is another and an important question. Improvements in boats and in management may very well be possible. Had the timbers of the Ramsgate boat which was injured the other day been somewhat stouter she might have escaped with a mere submersion. So with other like matters of detail. When, again, we come to structural design we touch a vital matter. In this respect it would seem clear that the lifeboat has reached an important stage in its evolution. Steam, which has altered so greatly all our means of transport, is here also asserting its superiority. The idea of a steam lifeboat is probably not a new one. Of late it appears to have ripened in a most practical form in the construction of a hydraulic steam lifeboat independent of paddles, screws, and even rudder, capable of considerable speed in any kind of weather, of lateral movement which enables her to maintain her position safely beside a wreck, and commodious enough to convey thirty persons besides her crew. Such a craft certainly marks a great advance in construction. She would as certainly cost much more than an ordinary lifeboat, and this fact will doubtless postpone for some time her adoption into the life-saving service. There appears no reason, however, why the advantages claimed for her should not be more fully tested in actual use than they have been, and we doubt not she will ere long find her place at some of the more dangerous of our coast stations. It will be long before the rowboats which have done such excellent work are quite superseded. A difficulty in the way of their proposed successors, it seems to us, will be found in the management of the steam apparatus in case a vessel of this type should capsize. If this obstacle be overcome steam launches of the new pattern may very probably become the lifeboats of the future.

TUMOUR OF THE SPINAL CORD.

TWO cases of considerable interest have lately been read before the New York Neurological Society. The first, reported in the *Medical News* of Jan. 12th by Drs. Holt and Herter, was a case of "Rapid Gliosis of the Spinal Cord." The patient was a child aged one year with a good family history, in whom, three months before coming under observation, a weakness was noticed in the right arm and hand, and the head began to droop forward. The motor paralysis in the right arm gradually increased, and finally there was complete loss of power in both arms and in the shoulder muscles, with atrophy. The muscles of the neck were exceedingly rigid and the head was carried stiffly slightly in advance of the normal position, with the face looking directly forwards. There seemed to be some loss of power in the legs. The knee-jerks were exaggerated. Ankle-clonus was present. There was considerable dyspnoea. The temperature showed irregular daily variations ranging from 100° to 105° F., and even higher. There was occasional vomiting. The pupils were equal, normal in size, and responsive to light. There was partial analgesia of the body below the arms. After the lapse of a month slight strabismus was noticed, and the head was rolled continuously from side to side. At times there was marked cyanosis, the respiration ranging from 32 to 52 per minute; the temperature rose to 106° and death took place. Upon post-mortem examination a greyish projecting mass was found occupying almost the entire right side of the medulla and a large portion of the left side. The medulla was considerably enlarged from before backwards, and from side to side. There was also considerable enlargement of the cord as far down as the eighth cervical segment, and from this point to the sixth dorsal there was some enlargement; below this the cord appeared to be

normal. Histological examination revealed a typical gliomatous structure, which involved to a greater or less extent the medulla and almost the entire cord. The second case was recorded by Drs. van Gilson and Fisher (*Medical News*, Jan. 19th). The patient was a man aged sixty-one years, with a negative family history, but a personal history of syphilis at the age of twenty-five, who for about six months before coming under observation had suffered from pronounced dizziness on standing erect. There was diplopia of three years' duration. For eight months there had been retention of urine and frequent severe attacks of diarrhoea. There was no weakness or ataxia of the upper extremities, but progressive loss of power in the lower of about one year's standing. There was a feeling of numbness from the waist downwards. Coördination in the lower extremities was impaired, the patient being unable to stand erect and falling to the floor unless supported. The gait was markedly ataxic. There was a gradual loss of sensation to touch and pain in both feet. The knee-jerk on the right side was absent, but was present on the left. Finally a large bed sore developed over the sacrum, and death soon followed. The post-mortem examination disclosed an extra-medullary tumour of the spinal cord, measuring a little more than an inch in its broadest part and extending from a little above the second lumbar segment downwards into the cauda equina, a distance of nearly three inches. It rested on the ventral surface of the cord and at about the level of the fourth lumbar segment. There was some distortion of the cord, especially at the fifth lumbar segment, both the anterior and posterior horns being compressed into a thin mass. The neoplasm proved to be a gliosarcoma.

THE WATER CARRIAGE OF SEWAGE.

MR. CHARLES TATTERSALL, the medical officer of health of Oldham, has just presented to his sanitary authority a concise report upon the above subject, a report much on the same lines as that made recently to the Nottingham sanitary authority by Dr. Boobyer, which we noticed in a recent issue.¹ The conclusions, too, at which Mr. Tattersall arrives are, in the main, similar to Dr. Boobyer's. Returns as to the methods of excrement disposal were obtained from thirty-eight large towns, and of this number six have always had the water carriage system, six have converted their systems to water carriage, sixteen are in process of converting their systems, and two are considering the expediency of so doing; in other words, thirty out of the thirty-eight towns reported upon have adopted or are adopting the water carriage system. In only four of the towns where conversion is going on does the corporation afford financial assistance to the owners of houses. In Hanley £1 is allowed for each pail converted into a water closet; at Accrington £2, and at Sheffield two-thirds of the cost of conversion; at Ashton-under-Lyne allowance is in some instances made for the cost of the closet on new property. Waste-water closets have been introduced in varying degree in twenty of the thirty-eight towns referred to. Mr. Tattersall summarises for the sanitary committee the pros and cons in regard to the ordinary type of water-closet, trough closets, and waste-water closets. In discussing the latter he goes fully into all the arguments for and against their use, but he is obviously convinced, both by the evidence adduced and by his own observations, that waste-water closets are under certain conditions of high value. He finally expresses his opinion that the adoption of water carriage for sewage would be found advantageous to the public health and economical to the sanitary authority. The best results would, Mr. Tattersall thinks, be obtained by

(1) the conversion of stacks of privies into troughs with automatic flush tanks, under the control of the corporation; (2) the conversion of existing privies situated in yards attached to single dwellings into waste-water closets of some approved type; and (3) the provision on new property of ordinary water-closets or waste-water closets, preferably the former. We notice that, like Dr. Boobyer, Mr. Tattersall refrains from specifically recommending any particular make of apparatus. There is no doubt that, as Dr. Boobyer remarks, it is best to simply retain the right of vetoing any unsuitable pattern.

CHOLERA IN CONSTANTINOPLE.

THE Turkish papers of the 5th inst. officially announce the outbreak of cholera in Constantinople. According to the official lists three cases were reported between Jan. 31st and the 2nd inst., of which one occurred among the infantry. On the 2nd and 3rd inst. there were six cases, of which two occurred among the troops. Only three cases have been fatal. An official communication was published in Constantinople on the 6th, containing instructions with regard to the prophylactic measures to be taken. A telegram from Athens informs us that on learning of the outbreak of cholera in Constantinople a quarantine of five days was decreed by the Greek Government against arrivals from the Turkish capital, and we understand that a similar regulation is in force at Madrid.

THE NEED OF REFORM IN WORKHOUSE ADMINISTRATION.

A STRIKING instance of the need of reform in workhouse administration as affecting the sick comes from the north of Sussex. In his half-yearly report to the guardians the medical officer enumerated many improvements which were required in the management of the house, and particularly as regarded the infirmary: No real nursing in the proper acceptance of the term and no night nursing, the insufficiency of surgical appliances, and the shortcomings of the bathing accommodation, were only a few of the faults referred to. But perhaps even worse than these was the mention by a member of the board that he found one inmate dying in bed, and that the other men in the ward were allowed to sit in their chairs as witnesses of the scene. These matters are to receive the immediate consideration of the guardians, and it would seem that as far as this particular workhouse is concerned the Local Government Board circular has come very opportunely. One by one boards of guardians in Sussex are supplying an efficient staff of nurses in the infirmaries, and we venture to hope that instances such as those just mentioned are of the past and not of the future.

GERMAN CONGRESS OF INTERNAL MEDICINE

THE Congress for Internal Medicine, which mostly assembles at Wiesbaden, is to hold its thirteenth annual meeting at Munich from April 2nd to 5th, under the presidency of Professor von Ziemssen. The general sittings on each of the three days—Tuesday, the 2nd, Wednesday, the 3rd, and Thursday, the 4th—will be given up, as usual, to predetermined subjects. This year the subjects selected are: 1. Ferruginous Therapeutics; to be opened by Professor Quincke of Kiel and Professor Bunge of Basle. 2. The Results of the Treatment of Diphtheria by Curative Serum; to be opened by Professor Heubner of Berlin. 3. The Pathology and Treatment of the Forms of Typhlitis; to be opened by Dr. Sahli of Berne and Dr. Helferich of Greifswald. Several papers of interest are already announced. Amongst them may be mentioned: Dr. A. Baginsky (Berlin), the Pathogenic Effects associated with the Serum Treatment of Diphtheria, an important question for which there should be much material now available; Dr. M. Litten (Berlin) on the Physiological and Clinical Significance of the Diaphragm Sign

¹ THE LANCET, Jan. 19th, 1895.

(Zwerchfellphänomen) with Demonstrations, a subject of some clinical interest which, we believe, was first drawn attention to last year by Dr. Litten at the Berlin Medical Society; Dr. T. Rumpf (Hamburg) on the Treatment of Typhus Fever with Dead Cultures of the Bacillus *Pyocyaneus*—we presume enteric fever (typhus abdominalis) is meant here; Dr. E. Sonnenburg (Berlin), Appendicitis Simplex; Dr. Semmola (Naples) on the Toxicity of Urine in its degree and “nosographisme” as a Factor in Diagnosis and Prognosis in Disease generally, and especially in Acute Infectious Diseases; Dr. O. Bollinger (Munich), the Causes of Death in Pneumonia; Dr. Smith (Schloss Marbach) on Alcohol in Therapeutics; Dr. Mordhorst (Wiesbaden), contribution to the Chemistry of Uric Acid and the Origin of Attacks of Gout; and Dr. Seifert (Würzburg) on Bronchial Stenosis. The permanent secretary of the Congress is Dr. Emil Pfeiffer of Wiesbaden, and the executive committee consists of Drs. Bäumler, Mosler, Schmidt, and Quinke.

DIPHTHERIA IN LONDON.

THE deaths from diphtheria in London last week showed further fluctuation, having declined from 45 to 34, though still 2 above the corrected average. Of the total 26 were in children aged between one and five years; and 4 each belonged to Poplar, Battersea, and Greenwich, and 3 each to St. Pancras, L'mehouse, and Camberwell sanitary areas. The per case mortality last week was as high as 31.5. The admissions to hospital numbered 49, against 74, 72, and 76 in the preceding three weeks, but were less than half the total fresh cases heard of, and Saturday night last found just 500 patients still under treatment. In Greater London also the deaths from diphtheria showed notable decline, 7 only being recorded—namely, 3 in West Ham and 2 each in Edmonton and Bromley districts.

A RECEPTION HOUSE FOR ST. GEORGE-THE-MARTYR, SOUTHWARK.

THE duty imposed upon metropolitan sanitary authorities by Section 60 of the Public Health (London) Act, 1891, of providing temporary shelter for families whose houses are being disinfected is one of the most important in the Act, and we imagine that medical officers of health under the Public Health Act, 1875, must often regret that a similar duty is not incumbent upon provincial sanitary authorities. Certainly all who have had experience of sanitary administration must have over and over again had reason to deplore their utter helplessness in dealing effectually with tenements of one or two rooms where cases of infectious diseases have occurred. There is, we are glad to see, a good prospect of the parish of St. George-the-Martyr soon adding a shelter to its public health defences, and the district medical officer of health, in recent report on the proposed shelter, puts the facts in regard to the matter in a very lucid manner before the sanitary authority. In illustration of the impossibility of efficient disinfection in many cases he points out that between June 1st, 1892, and Dec. 31st, 1894, there were 610 persons occupying infected tenements of one room, 1357 of two rooms, and 461 of three rooms; and in all these cases disinfection could not be properly carried out. In other words, within the last two years and a half no less than 526 infected tenements, occupied by 2428 persons, have not been properly disinfected. It would be of much interest to ascertain whether in many of these cases secondary attacks of infectious disease have occurred after the return of patients from hospital, as it would seem to be by no means unlikely that on the return of a patient infected clothing and articles might be again brought into use and exposed. Dr. F. J. Waldo, in urging the claims of such a shelter, refers to its economical aspects, and he thinks that such provision will ultimately lower the rates instead of raising them by pro-

viding fewer inmates for the workhouses and fever hospitals. The plea of poverty cannot, Dr. Waldo contends, be any longer urged by the poorer sanitary districts of the metropolis as an excuse for inaction in carrying out the provisions of the Public Health (London) Act, 1891, inasmuch as the operations of the Equalisation of Rates Act, 1894, will very materially assist those districts which hitherto have had difficulty in the matter of expenditure.

THE REMOVAL OF BONE IN THE MICRO-CEPHALIC SKULL.

IN a paper on the microcephalic or idiot skull and the macrocephalic or hydrocephalic skull, contained in the recent number of the *Journal of Anatomy and Physiology*, Sir George Humphry remarks that in none of the nineteen specimens of idiot skulls of which details are given is there anything to suggest that the deficiency in the development of the skull was the leading feature in the deformity and that the smallness of the bony cerebral envelope exerted a compressing or dwarfing influence upon the brain, or anything to give encouragement to the practice lately adopted in some instances of removal of a part of the bony case, with the idea of affording more space and freedom for the growth of the brain. In these, as in other instances of man and the lower animals, the brain growth is the determining factor, and the skull grows upon and accommodates itself to the brain whether the latter be large or small. This view is corroborated by the fact that, in the brains taken from the two idiot skulls in St. Bartholomew's Hospital, as well as in other instances, as those shown by Professor Cunningham, the convolutions of the brain give no indications of compression, but are free, outstanding, and separated by well-marked sulci.

“ANAGLYPHS.”

SEVERAL remarkable pictures termed “anaglyphs” have been submitted to us. They are printed in two colours, red and blue, the two images of the same object overlapping each other laterally to about three-sixteenths or one-quarter of an inch, and vertically either to about one-sixteenth of an inch or scarcely perceptibly. The pictures are looked at through a binocular eyeglass, one of the glasses being red, the other of a peculiar deep violet blue or blue purple. The overlapping of the images gives to the pictures when examined with the naked eye, a confused, blotchy appearance; but when looked at through the glasses the blotchiness disappears, and instead of it, with a clear outline, the most perfect stereoscopic effect is produced. The reason of this appears to be that the prevailing tone of the pictures is red, whilst the chief outlines are strongly defined in white. These are, of course, seen through the red glass. The blue outline is much fainter, and hence, although it ought to be seen through the blue glass, becomes imperceptible owing to the deep tone of this glass. Only the stronger white and dark outlines can be easily seen through the blue glass. The main outlines, as well as the details, are seen essentially through the red glass, but by skilfully shading the red lines with blue an effect of distance is secured, and the stereoscopic effect is thus in part produced. The best of the pictures we have examined is that of the “Salle de Sculpture—Musée du Luxembourg,” which has the curious effect when inverted of bringing the background forwards and throwing the figures back.

CEREBRAL TUMOUR OF ACUTE ONSET.

AT a meeting of the Berliner Gesellschaft für Psychiatrie und Nervenkrankheiten Dr. Bruns recently showed a cystic angioma of the brain which had been removed from the left-leg centre in the posterior central convolution, close to the middle line. He had at first, on account of the absence of

the classical symptoms of tumour and on account of the fact that the onset of symptoms had been acute, thought that the cause of the symptoms was encephalitis rather than tumour; but as no improvement took place an operation was decided upon. The cortex of the central convolutions was healthy. The foot centre—there had been cramps starting in the right foot—was then determined electrically, and an incision made. A tumour was at once evident, and this was removed, together with some brain substance. In the evening and on the next day there was no increase in weakness or impairment of ordinary or of muscle sensibility. The patient unfortunately died from septic meningitis, and the necropsy showed that the rest of the brain was quite healthy. The interesting points in the case are that it was one of tumour without any of the usual symptoms and with quite a sudden onset. The condition after operation, in which presumably there had been removal of a certain part of the cortex, is also interesting because of the absence of any sensory disturbance as a result of this.

TRIONAL.

AN abstract of an important contribution on the action of trional by Dr. K. Rychlinski appears in a recent number of the *Neurologisches Centralblatt*. Fourteen cases of sleeplessness due to various causes, chiefly psychical conditions, were treated with this drug, and at different times sulphonal, chloral hydrate, and duboisin were substituted, and their effect compared with that of trional. He found that in certain cases of long-continued insomnia trional in doses of from one-half to one gramme was efficacious without producing any headache; whereas in the same cases ordinary doses of chloral hydrate or sulphonal were inefficacious and larger doses only procured a short sleep. In certain cases the dose was limited to one gramme, but in only two of the fourteen cases were large doses of four grammes necessary in order to procure unbroken sleep for eight or ten hours, and in those cases chloral hydrate and sulphonal were more efficacious in smaller doses of two or three grammes. Trional in hot milk or tea procured eight hours' sleep usually within half an hour. Sometimes, however, its effect was not produced until two hours after administration. Several times dose took effect also on the second night, but only when a large dose was administered. In a case of mitral regurgitation there was no evidence of any bad effect produced on the heart, and this was confirmed by sphygmographic tracings. Although further experience of this drug is still requisite it cannot be denied that experiences such as those recorded in this paper suggest that in trional we may find a safe, efficient, and reliable hypnotic.

MEDICAL WITNESS AND JUDGE.

ON Feb. 8th, at the Winchester Assize, before Mr. Justice Cave, a labourer named Cousins was indicted with having attempted to carnally know a girl aged ten years. The jury found the prisoner guilty, and he was sentenced to eighteen months' hard labour. The case is of interest to the medical profession on account of the severe strictures passed on the medical testimony by the judge. Dr. L. Maybury and Mr. Colt gave it as their opinion that "there was no evidence that penetration had occurred," whereupon Mr. Justice Cave remarked that the witnesses were attempting to decide the case and so usurping the province of the jury. It seems to us that the conflict between the judge and the medical witnesses unfortunately arose through the latter—no doubt unintentionally—stating there was no evidence of penetration. What they intended to say was that the evidence as obtained from an examination of the prosecutrix was not conclusive, since the hymen was not ruptured and there was no laceration or bruising of the parts. At the same time there was presumptive evidence of the act, for the vulva were inflamed

and there was a purulent discharge, and on the shirt of the prisoner the microscope revealed semen, pus, and epithelial scales. We regret that the learned judge did not take a more generous view of the medical evidence, instead of practically ascribing an interested motive. Nevertheless, the incident should form a valuable object-lesson of the importance, especially in criminal cases, of using correct phrases and of drawing logical inferences.

PSEUDO-BULBAR PARALYSIS.

DR. SACAZE of Montpellier records in the *Revue de Médecine* the case of a patient who in consequence of two separate attacks suffered from left hemiplegia, hemi-chorea, aphasia, and aphonia, with great difficulty in swallowing, and paresis of the tongue and of the soft palate. The necropsy revealed areas of softening in both hemispheres, the internal capsule, the lenticular nuclei, and the caudate nuclei being destroyed on both sides. The pons and medulla, apart from commencing secondary degeneration of the pyramids, were quite normal. This case illustrates the fact, which has now frequently been pointed out, especially by Dr. Barlow and Drs. Hughlings Jackson and James Taylor in this country, that a lesion on each side of the cerebrum gives rise to symptoms which so closely resemble those of bulbar paralysis as to be clinically almost indistinguishable from these. The reason of this seems to be that whereas a unilateral lesion in the brain gives rise to only transitory and slight affection of the bilaterally associated movements, the occurrence of a second lesion on the opposite side of the brain so weakens those movements as to cause very distinct impairment of the oesophageal, laryngeal, palatal, and tongue movements, thus giving rise to symptoms which closely simulate those of bulbar paralysis.

THE DIFFUSION OF SMALL-POX.

THE new cases of small-pox notified in London last week were 11 in number, and the admissions to institutions of the Metropolitan Asylums Board were 18, against 6, 8, and 21 in the preceding three weeks respectively. The disease continues to prevail in the parish of Marylebone, to which belonged the 3 deaths from small-pox registered in London during the week. On Saturday last there remained 56 cases of small-pox under treatment, an increase of 5 on the total on the preceding Saturday. Last week witnessed an increase of fresh cases in West Ham, where over 6 attacks were chronicled. One or two cases came to light in other suburban districts. A dozen attacks at Birmingham show that the disease is getting under control there; and, moreover, no death was registered. Generally the midland districts were free, as compared with recent weeks. In Scotland small-pox continues to spread in Glasgow. A death occurred on Wednesday of last week in the person of a sailor from London, and 4 fresh cases came to light, followed by 2 more the next day; when also two persons were dismissed from the infirmary, having been admitted under a mistaken diagnosis. The total cases in the city were then 39 in number. In Edinburgh there were 25 patients known to be under treatment in the middle of last week, 7 cases having been notified since Jan. 27th. In Govan and Auchterarder stray cases have recently been discovered. In Dublin in the week ended the 2nd inst. 69 cases were admitted to hospital, 64 discharges took place, and 171 patients were left under treatment, 131 additional convalescent cases being under isolation at Killmainham. Five deaths occurred, including 2 in vaccinated persons (aged nine and fifty years respectively) and 2 in unvaccinated persons, both under ten years of age. A total of 108 deaths had been reached up to the date in question. Much good will, it is hoped, be effected by the very stringent order of Archbishop Walsh as to the disabilities of persons in the

matters of school attendance and confirmation if not vaccinated or revaccinated as their age may require. In December no fewer than 127 streets were invaded by small-pox—30 on the north side and 97 on the south side of the Liffey. The admissions to hospital were 262 in number, the notified cases 210, and 26 deaths were registered. All possible steps are being taken to prevent the spread of the disease, and 56 persons were at the close of the year occupied in the removal of patients and in the necessary processes of disinfection. In the fourth quarter of 1894 the admissions to hospital numbered 466 and the deaths registered 51, including 27 unvaccinated sufferers under five years of age.

THE ROWLANDSON EXHIBITION.

the comic portrait painter of the eighteenth century whom he intended to bring into ridicule as the victims of acromegaly? Acromegaly is still of sufficiently frequent occurrence, yet to the eyes of Rowlandson, Bunbury, may mankind could best be brought into contempt by painting them with the *facies* of the disease as they had derived it from their imagination. The immensely lengthened, the projection of the under jaw and lip, the low forehead, the sunken eyes, the large ears, the swollen face are there, and placed on paper a hundred years before the pathological condition was known to our profession. And this becomes more astonishing when we remember that the artists of those days were not idealists, but that without any modern pretensions to realism they painted what they thought they saw. And that they really saw the human face, whether wrung into distortion for purposes of caricature or graciously smoothed out for purposes of flattery, to be different from what we see it, is proved to our minds by the fact that Reynolds's and Gainsborough's courtly creations have the same similarity to each other that we have described as being present in the work of the caricaturists. Except to a connoisseur, who may be guided by some trick in brush-work, it is often difficult to see the difference between the Duchess of Dashire with hoop by Reynolds and the Marchioness of Blankaster with dog by Gainsborough. Those interested in Rowlandson's work had an excellent opportunity recently of seeing a collection of his drawings at the Fine Art Society in Bond-street.

Famous as a caricaturist, he was there seen in his less known character of a graceful portrait painter, but the characteristic countenances were not without numerous examples.

PYLOROPLASTY.

IN THE LANCET of July 9th, 1892, Dr. Limont and Mr. Page published an account of the first case of pyloroplasty performed in this country. In the following May Mr. Pearce Gould¹ published also in this journal an account of a case in which he had repeated Mikulicz's operation and entered more fully into its details and advantages. He also collected a series of twenty-two other cases by various American and Continental surgeons. In a recent *brochure* Dr. Corazza of Verona records a successful case of his own, and adds a series of twenty-seven other cases by Continental surgeons. Together with Mr. Miller's case recorded in THE LANCET of Dec. 1st, 1894, and Mr. Morison's case published in our columns to-day, we obtain a total of fifty-three cases in which pyloroplasty has been carried out for pyloric stenosis. Of these, six have proved fatal—two from collapse, three from sepsis, and one from internal hæmorrhage consecutive to the operation. These figures show an exceedingly satisfactory result, and there is reason to look for a still further improvement if the patients are submitted to operation at an earlier period of the affection and with more perfect observance of complete asepsis. The restoration of the function of the stomach is a different matter from mere recovery from the operation, and the published reports of the cases are not in all cases complete in this respect, nor have they been made sufficiently long after the operation to permit of a full statement on this head. But here, too, early operation is likely to yield far better results than when the disease has been allowed to progress almost to a lethal point before operation is resorted to.

DIPHTHERIA AT MITCHAM.

DR. MAIR, the medical officer of health to the Croydon Rural District Council, has presented a report to his health committee upon the prevalence of diphtheria in Mitcham during 1894, which contains some instructive facts. Out of a total of 64 cases notified in the whole district during the year, no fewer than 53 occurred in Mitcham and the adjoining part of Merton, the number of houses invaded being respectively thirty-seven and twenty-seven for the same areas. Dr. Mair very properly points to the disparity between invaded households and cases as a pressing need for an isolation hospital. As regards the disproportionate incidence in Mitcham and its vicinity the facts point clearly to school infection, children attending one particular school in the district from twenty-one out of the twenty-seven invaded houses, yet in eleven of these the child first attacked did not attend school. Dr. Mair thinks, therefore, that a wider explanation is to be found in the drainage conditions, not only of the school, but of the whole of the affected portion of Mitcham. Owing to the defects in gradients and connexions there is an actual influx of sewage from the main sewer into the drains during flood times. His advice that everything should be done to remedy this "heading back" of the sewage at all costs is therefore thoroughly warranted; and in further proof of the unhealthiness of the area it may be remarked that an inspection of 318 children attending the school in question resulted in the discovery that 243, or nearly 77 per cent., had "unhealthy throats." Chronic tonsillitis and a certain proportion of granular throats were the prevailing conditions. It is not surprising then that diphtheria should have found a footing
